

Propagation of chaos for interacting particles subject to environmental noise

Michele Coghi and Franco Flandoli

Abstract

A system of interacting particles described by stochastic differential equations is considered. Opposite to the usual model, where the noise perturbations acting on different particles are independent, here the particles are subject to the same space-dependent noise, similarly to the (non-interacting) particles of the theory of diffusion of passive scalars. We prove a result of propagation of chaos and show that the limit PDE is stochastic and of inviscid type, opposite to the case when independent noises drive the different particles.

Key words and phrases - Interacting particle system, propagation of chaos, mean field limit, Kraichnan noise, Wasserstein metric.

1 Introduction

We prove a propagation of chaos result for the interacting particle system in \mathbb{R}^d described by the equations

$$dX_t^{i,N} = \frac{1}{N} \sum_{j=1}^N K \left(X_t^{i,N} - X_t^{j,N} \right) dt + \sum_{k=1}^{\infty} \sigma_k \left(X_t^{i,N} \right) \circ dB_t^k \quad (1)$$

$$i = 1, \dots, N$$

where $K, \sigma_k : \mathbb{R}^d \rightarrow \mathbb{R}^d$, $k \in \mathbb{N}$, are uniformly Lipschitz continuous and $(B^k)_{k \in \mathbb{N}}$ are independent real-valued Brownian motions on a filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$; the additional assumption Hypothesis 1 will be imposed on σ_k 's, in Section 2. In (1) we chose Stratonovich stochastic integration since the final result, in Stratonovich form and under Hypothesis 1, is more clear and elegant. However, at the price of additional terms, the results hold for the Itô case and under more general assumptions (for instance time-dependent σ_k), see Section 2.3.

The classical propagation of chaos framework considered in the literature deals with the system

$$dX_t^{i,N} = \frac{1}{N} \sum_{j=1}^N K \left(X_t^{i,N} - X_t^{j,N} \right) dt + dW_t^i \quad (2)$$

$$i = 1, \dots, N$$

where $(W^i)_{i \in \mathbb{N}}$ are independent \mathbb{R}^d -valued Brownian motions; see for instance [19]. Opposite to this classical case, in (1) *the same* space-dependent delta-correlated-in-time noise $v(t, x)$, formally given by

$$v(t, x) = \sum_{k=1}^{\infty} \sigma_k(x) \frac{dB_t^k}{dt}$$

acts on each particle. This type of space correlated noise was introduced in Physics to describe small scale motion in a turbulent fluid, like in the famous Kraichnan's model of the sixties. The physical intuition in this case, for equation (1), is that the particles are embedded in a turbulent fluid with velocity $v(t, x)$. Each particle is subject to the transport effect of the fluid and to the motion caused by the interaction with the other particles. Among other examples, we may also think of the case of smoothed point vortices (think of

relatively large scale vortex structures in ocean or atmosphere), subject to the transport effect of each other (the interaction) and of a background, small scale, turbulent perturbation. Instead of considering all fluid scales as a whole, described by classical equations of fluid dynamics, one could try, phenomenologically, to separate the large scale vortex structures from the small scale more irregular fluctuations and consider the small scales modeled independently a priori, and the vortices just influencing each other and influenced by the small scales, without feedback on small scales. In such an example, to fit with the assumptions of model (1), we have to assume that the interaction between vortices is described by a smoothed Biot-Savart kernel, since the singularity of the true Biot-Savart kernel introduces additional difficulties which cannot be handled with the techniques of this paper. Opposite to such kind of applications, the more classical model (2) is more suitable when each particle has its own internal origin of randomness (like certain living organisms) or the external sources of randomness can be considered as totally uncorrelated at the scale of the particles, like for very light macroscopic particles interacting with the molecules of a gas.

If the covariance of the noise is suitably concentrated (see Hypothesis 1 in Section 2), the random field $v(t, x)$ is poorly space-correlated, except at very short distances and thus particles which occupy sufficiently distant positions are subject to almost independent noise, a fact that makes the two systems (1) and (2) not so different when the collection of particles is sufficiently sparse.

However, in the limit when $N \rightarrow \infty$, the behavior is completely different. Let $(X^i)_{i \in \mathbb{N}}$ be a sequence of i.i.d. random vectors in \mathbb{R}^d with law μ_0 ; assume that the families $(B^k)_{k \in \mathbb{N}}$ $((W^i)_{i \in \mathbb{N}}$ for equation (2)) and $(X^i)_{i \in \mathbb{N}}$ are independent and take $X_0^{i,N} = X^i$ as initial conditions for system (1). Denote by S_t^N the empirical measure defined as

$$S_t^N = \frac{1}{N} \sum_{i=1}^N \delta_{X_t^{i,N}}. \quad (3)$$

The random probability measure S_0^N converges weakly to μ_0 in probability. In both cases of equations (1) and (2) one can prove (cf. [19] for case (2) and the present paper for case (1)) that S_t^N converges weakly, in probability, to a probability measure μ_t . However, in case (2), μ_t is deterministic, the weak convergence of S_t^N to μ_t is understood in probability with respect to both initial conditions and noise, and μ_t is a distributional solution of the nonlinear equation

$$\frac{\partial \mu_t}{\partial t} + \operatorname{div}(b_{\mu_t} \mu_t) = \frac{1}{2} \Delta \mu_t$$

where, for a generic probability measure ν , the vector field $b_\nu : \mathbb{R}^d \rightarrow \mathbb{R}^d$ is defined as

$$b_\nu(x) = \int_{\mathbb{R}^d} K(x-y) \nu(dy).$$

On the contrary, in case (1), μ_t is a random probability measure and, under the particular assumptions of Section 2.1, it satisfies in the distributional sense the stochastic PDE

$$d\mu_t + \operatorname{div}(b_{\mu_t} \mu_t) dt + \sum_{k=1}^{\infty} \operatorname{div}(\sigma_k \mu_t) \circ dB_t^k = 0 \quad (4)$$

and the weak convergence of S_t^N to μ_t is understood in probability only with respect to the initial conditions. In Section 2.1 we give the Itô form of this stochastic partial differential equation and in Section 2.3 we show the modifications when we start from (1) in Itô form or when the assumptions on σ_k are more general than those of Section 2.1.

The main result of this paper is the following theorem, by mean of which one can relate the convergence of the empirical measure of the system with the convergence of the empirical measure of the initial conditions.

Theorem 1. *Let $T > 0$ and assume Hypothesis 1, given in Section 2 on the noise. There exists a constant $\tilde{C}_T > 0$, such that*

$$\mathbb{E}[W_1(\mu, S_t^N)] \leq \tilde{C}_T \mathbb{E}[W_1(\mu_0, S_0^N)]$$

where W_1 is the Wasserstein distance (see Definition 9).

In Section 4 is given a more precise statement of Theorem 1, as well as a short discussion on recent results on quantitative estimates on the rate of convergence of S_0^N to μ_0 which can be applied in our model.

From Theorem 1 we deduce a *conditional* propagation of chaos result: Conditional to $(B^k)_{k \in \mathbb{N}}$, the particles tend to be independent as $N \rightarrow \infty$. One can find other works in literature dealing with conditional propagation of chaos, but referring to different objects and in different contexts. In [4] and [11] the authors threat propagation of chaos conditionally to product measures on the Kac's sphere and in the latter are given quantitative estimates. In other works the conditionality is given with respect to the σ -field of the permutable events, see e.g. [20] and [7].

The precise statement about conditional propagation of chaos in this work is given by the following theorem.

Theorem 2. *Let \mathcal{F}_t^B be the filtration associated to $(B^k)_{k \in \mathbb{N}}$. We suppose that the noise satisfies Hypothesis 1, in both equation (1) and (4). There exists a random measure-valued solution μ_t of equation (4) such that*

$$\lim_{N \rightarrow \infty} E \left[\left| \langle S_t^N, \phi \rangle - \langle \mu_t, \phi \rangle \right| \right] = 0$$

for all $\phi \in C_b(\mathbb{R}^d)$.

Moreover, given $r \in \mathbb{N}$ and $\phi_1, \dots, \phi_r \in C_b(\mathbb{R}^d)$, we have

$$\lim_{N \rightarrow \infty} E \left[\phi_1(X_t^{1,N}) \dots \phi_r(X_t^{r,N}) \middle| \mathcal{F}_t^B \right] = \prod_{i=1}^r \langle \mu_t, \phi_i \rangle$$

in $L^1(\Omega)$.

In particular, for every $r \in \mathbb{N}$ and $\phi \in C_b(\mathbb{R}^d)$, $\lim_{N \rightarrow \infty} E \left[\phi(X_t^{r,N}) \middle| \mathcal{F}_t^B \right] = \langle \mu_t, \phi \rangle$, namely the conditional law of $X_t^{r,N}$ given \mathcal{F}_t^B converges weakly to μ_t . We can also prove:

Theorem 3. *Given μ_t as in Theorem 2 and $r \in \mathbb{N}$, if X_t is the unique strong solution of the SDE*

$$dX_t = b_{\mu_t}(X_t) dt + \sum_{k=1}^{\infty} \sigma_k(X_t) dB_t^k, \quad X_0 = X_0^r$$

where the noise satisfies Hypothesis 1, then

$$\lim_{N \rightarrow \infty} E \left[\left| X_t^{r,N} - X_t \right| \right] = 0.$$

Moreover μ_t is a version of the conditional law of X_t with respect to \mathcal{F}_t^B , namely

$$\langle \mu_t, \phi \rangle \in \mathbb{E} \left[\phi(X_t) \middle| \mathcal{F}_t^B \right]$$

for every $\phi \in C_b^\infty(\mathbb{R}^d)$.

The result is similar to the case of a *deterministic* environment acting on the particles, which could be modelled by the equations

$$\begin{aligned} \frac{dX_t^{i,N}}{dt} &= \frac{1}{N} \sum_{j=1}^N K(X_t^{i,N} - X_t^{j,N}) + v(t, X_t^{i,N}) \\ i &= 1, \dots, N. \end{aligned}$$

As it was shown by [8], this system satisfies a propagation of chaos property with the limit deterministic inviscid PDE

$$\frac{\partial \mu_t}{\partial t} + \operatorname{div}(b_{\mu_t} \mu_t) dt + \operatorname{div}(v(x) \mu_t) = 0.$$

Also some technical steps of our proof are strongly inspired by [8]. Moreover, with a different proof and partially a different purpose, some of the technical steps about existence and (especially) stability results for measure-valued stochastic equations have been proved before by [14], [15], [17].

We do not treat here a number of additional interesting questions that are postponed to future works, like: i) the fact that μ_t should have a density with respect to Lebesgue measure if this is assumed for μ_0 ; ii) the uniqueness of solutions to the SPDE (8) (which seems to be true in some class of integrable functions when μ_0 has an integrable density, but it is less clear in spaces of measure-valued solutions); iii) possible generalizations to non-Lipschitz continuous interaction kernel K . In particular, the problem of propagation of chaos for system (1) when $K(x) = \frac{x^\perp}{|x|^2}$, corresponding to point vortices in 2D inviscid fluids, has been posed by [10] and seems to be a challenging question.

In Section 2, we will give some informations about the settings in which we study the problem. Section 3 will be devoted to the study of existence and uniqueness of equation (4) using its Itô version. Finally in Section 4 we will study the convergence and propagation of chaos results.

2 Precise setting of the problem

2.1 Assumptions on the noise

We will now state the assumptions which we will consider on the noise. Recall that $\sigma_k : \mathbb{R}^d \rightarrow \mathbb{R}^d$ is a vector field, for every $k \in \mathbb{N}$.

Hypothesis 1. i) $\sigma_k : \mathbb{R}^d \rightarrow \mathbb{R}^d$ are measurable and satisfy $\sum_{k=1}^{\infty} |\sigma_k(x)|^2 < +\infty$, for every $x \in \mathbb{R}^d$.

ii) σ_k is a C^2 divergence free vector fields, i.e.

$$\operatorname{div} \sigma_k = 0, \quad \forall k \geq 1$$

Define the matrix-valued function $Q : \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$ as

$$Q^{ij}(x, y) := \sum_{k=1}^{\infty} \sigma_k^i(x) \sigma_k^j(y). \quad (5)$$

iii) with a little abuse of notation, there exists a function $Q : \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$ such that

- (a) $Q(x, y) = Q(x - y)$ (space homogeneity of the random field $\varphi(t, x) = \sum_{k=1}^{\infty} \sigma_k(x) B_t^k$)
- (b) $Q(0) = Id$
- (c) $Q(\cdot)$ is of class C^2 with second derivatives uniformly bounded in the euclidean norm of $\mathbb{R}^{d \times d}$, i.e. $\sup_{x \in \mathbb{R}^d} |\partial_{x_i x_j}^2 Q(x)| < +\infty$. Here we are using the Hilbert-Schmidt norm on the space of the matrices.

One can find examples of this model in several references, e.g. [6] and [12]. We recall here the most important properties of this type of noise and we give an explicit exemple.

Remark 4. Under the previous assumptions we have

$$\sum_{k=1}^{\infty} |\sigma_k(x) - \sigma_k(y)|^2 \leq L_\sigma^2 |x - y|^2 \quad \text{for all } x, y \in \mathbb{R}^d \quad (6)$$

for some constant $L_\sigma > 0$. Indeed,

$$\sum_{k=1}^{\infty} |\sigma_k(x) - \sigma_k(y)|^2 = 2\operatorname{Tr}(Q(0)) - 2\operatorname{Tr}(Q(x - y)).$$

The function $f(z) = \operatorname{Tr}(Q(z))$ has the property $f(-z) = f(z)$, hence from the identity $2f(z) = f(z) + f(-z)$ and Taylor development of both $f(z)$ and $f(-z)$ we get $2f(z) = 2f(0) + \langle D^2 f(0) z, z \rangle + o(|z|^2)$ which implies $\sum_{k=1}^{\infty} |\sigma_k(x) - \sigma_k(y)|^2 \leq C_1 |x - y|^2$ if $|x - y| \leq 1$, for a suitable constant $C_1 > 0$. When $|z| > 1$ we have $f(z) \leq C_2 |z|^2$ for a suitable constant $C_2 > 0$, because $Q(\cdot)$ has bounded second derivative. Hence $\sum_{k=1}^{\infty} |\sigma_k(x) - \sigma_k(y)|^2 \leq C_2 |x - y|^2$ when $|x - y| > 1$. This proves (6) with $L_\sigma^2 = \max(C_1, C_2)$.

It is also important to notice that the covariance function Q can be given first. Indeed Theorem 4.2.5 of [12] states that any matrix valued function $Q : (x, y) \rightarrow Q(x, y)$ satisfying (6) can be expressed in the form (5). A very common exemple of this kind of noise is the Isotropic Random Field, which we will present now.

Example 5. Let $d \geq 2$ and $f \in L^1(\mathbb{R}_+)$ such that $\int_{\mathbb{R}^d} |y|^2 f(|y|) dy < +\infty$. Given $\pi(y)$ a $d \times d$ matrix defined as

$$\pi(y) = (1-p)Id_d + |y|^{-2}(pd-1)y \otimes y \quad \text{for } y \in \mathbb{R}^d, \quad p \in [0, 1],$$

we consider

$$Q(x) = \int_{\mathbb{R}^d} e^{iy \cdot x} \pi(y) f(|y|) dy \quad x \in \mathbb{R}^d$$

It is easy to see that property $ii) - a)$ is satisfied. Property $ii) - c)$ is true after a renormalization in L^1 of f and $ii) - c)$ can be verified with a straightforward computation.

Remark 6. A strong solution of system (1) is a continuous process $(X^{1,N}, \dots, X^{N,N})$, adapted to $(\mathcal{F}_t^B)_{t \geq 0}$, such that

$$P \left(\sum_{k=1}^{\infty} \int_0^T \left| \sigma_k \left(X_t^{i,N} \right) \right|^2 dt < \infty \right) = 1$$

for every $i = 1, \dots, N$ (so that the series of stochastic integrals converge in probability) and identity (1) holds in the integral sense. But $\sum_{k=1}^{\infty} \left| \sigma_k \left(X_t^{i,N} \right) \right|^2 = \text{Tr}(Q(0)) = d$, hence the sum of stochastic integrals in equation (1) always converges, even in mean square.

2.2 Itô formulation

In the Introduction, for the benefit of interpretation, we have formulated the interacting particle system and the limit SPDE both in Stratonovich form. However, for sake of rigor and mathematical simplicity, it is convenient to work in the corresponding Itô form. Under Hypothesis 1, the interacting particle system in Itô form is

$$\begin{aligned} dX_t^{i,N} &= \frac{1}{N} \sum_{j=1}^N K \left(X_t^{i,N} - X_t^{j,N} \right) dt + \sum_{k=1}^{\infty} \sigma_k \left(X_t^{i,N} \right) dB_t^k \\ i &= 1, \dots, N. \end{aligned} \tag{7}$$

and the SPDE (4) in Itô form is

$$d\mu_t + \text{div}(b_{\mu_t} \mu_t) dt + \sum_{k=1}^{\infty} \text{div}(\sigma_k(x) \mu_t) dB_t^k = \frac{1}{2} \Delta \mu_t. \tag{8}$$

which will be interpreted in weak form in Definition 11 below. At the rigorous level these are the equations to which the statements of Section 1 apply. Let us motivate the fact that (7) and (8) correspond to (1) and (4), under Hypothesis 1. This correspondence can be made rigorous but it requires (especially for (4)) proper definitions of solutions and a number of details. If we accept that (1) and (4) are given only for interpretation and the rigorous set-up is given by (7) and (8), an heuristic proof of their equivalence is sufficient. The correspondence between (1) and (7) is due to the fact that the Stratonovich integral $\int_0^t \sigma_k(X_s^{i,N}) \circ dB_s^k$ is equal to

$$\int_0^t \sigma_k(X_s^{i,N}) dB_s^k + \frac{1}{2} \int_0^t (D\sigma_k \cdot \sigma_k)(X_s^{i,N}) ds$$

(see [12]) where $(D\sigma_k \cdot \sigma_k)_i(x) = \sum_{j=1}^d \sigma_k^j(x) \partial_j \sigma_k^i(x)$. This correction term vanishes thanks to the assumption

$$\text{div } \sigma_k = 0 \quad \text{for each } k \in \mathbb{N}$$

(it is natural if we interpret $v(t, x)$ as the velocity field of an incompressible fluid) along with the assumptions on Q made above. Indeed

$$0 = \left(\sum_{j=1}^d \partial_j \right) Q^{ij}(0) = \sum_{k=1}^{\infty} \sum_{j=1}^d \partial_j \left(\sigma_k^j(x) \sigma_k^i(x) \right) = \sum_{k=1}^{\infty} \sum_{j=1}^d \sigma_k^j(x) \partial_j \sigma_k^i(x).$$

Therefore the Stratonovich and Itô formulations coincide for the interacting particle system.

Let us discuss now the correspondence between (4) and (8). The Stratonovich integral $\int_0^t \operatorname{div}(\sigma_k(x) \mu_s) \circ dB_s^k$ is formally equal to (one should write all terms applied to test functions)

$$\int_0^t \operatorname{div}(\sigma_k(x) \mu_s) dB_s^k - \frac{1}{2} \int_0^t \operatorname{div}(\sigma_k(x) \operatorname{div}(\sigma_k(x) \mu_s)) ds$$

(the second term, with heuristic language, is initially given by $\frac{1}{2} \int_0^t \operatorname{div}(\sigma_k(x) d\langle \mu, B^k \rangle_s)$ where $\langle \mu, B^k \rangle_s$ is the mutual quadratic covariation; then we use again equation (4) to compute $d\langle \mu, B^k \rangle_s$ and get $d\langle \mu, B^k \rangle_s = \operatorname{div}(\sigma_k(x) \mu_s) ds$). Now we see that

$$\sum_{k=1}^{\infty} \operatorname{div}(\sigma_k(x) \operatorname{div}(\sigma_k(x) \mu_s)) = \sum_{\alpha, \beta=1}^d \partial_{\alpha} \partial_{\beta} (Q^{\alpha\beta}(x, x) \mu_s) - \operatorname{div} \left(\left(\sum_{k=1}^{\infty} D\sigma_k \cdot \sigma_k \right) \mu_s \right) \quad (9)$$

where $D\sigma_k \cdot \sigma_k$ is the vector field with components

$$(D\sigma_k \cdot \sigma_k)^{\alpha} = \sum_{\beta=1}^d (\partial_{\beta} \sigma_k^{\alpha}) \sigma_k^{\beta}.$$

Indeed,

$$\begin{aligned} \sum_{k=1}^{\infty} \operatorname{div}(\sigma_k(x) \operatorname{div}(\sigma_k(x) \mu_s)) &= \sum_{k=1}^{\infty} \sum_{\alpha, \beta=1}^d \partial_{\alpha} \left(\sigma_k^{\alpha}(x) \partial_{\beta} \left(\sigma_k^{\beta}(x) \mu_s \right) \right) \\ &= \sum_{k=1}^{\infty} \sum_{\alpha, \beta=1}^d \partial_{\alpha} \partial_{\beta} \left(\sigma_k^{\alpha}(x) \sigma_k^{\beta}(x) \mu_s \right) - \sum_{k=1}^{\infty} \sum_{\alpha, \beta=1}^d \partial_{\alpha} \left((\partial_{\beta} \sigma_k^{\alpha})(x) \sigma_k^{\beta}(x) \mu_s \right) \end{aligned}$$

and $\sum_{k=1}^{\infty} \sigma_k^{\alpha}(x) \sigma_k^{\beta}(x) = Q^{\alpha\beta}(x, x)$. Moreover,

$$\sum_{k=1}^{\infty} (D\sigma_k(x) \cdot \sigma_k(x))^{\alpha} = \sum_{k=1}^{\infty} \sum_{\beta=1}^d (\partial_{\beta} \sigma_k^{\alpha}(x)) \sigma_k^{\beta}(x) = \sum_{\beta=1}^d \partial_{\beta} Q^{\alpha\beta}(x, x) - \sum_{k=1}^{\infty} \sigma_k^{\alpha}(x) \operatorname{div} \sigma_k(x). \quad (10)$$

In view of the next Section, we stress that until now we have not used Hypothesis 1. Under Hypothesis 1, we have $Q^{\alpha\beta}(x, x) = \delta_{\alpha\beta}$ and $\operatorname{div} \sigma_k = 0$, hence $\sum_{k=1}^{\infty} (D\sigma_k(x) \cdot \sigma_k(x))^{\alpha} = 0$ for all $\alpha = 1, \dots, d$, and finally

$$\sum_{k=1}^{\infty} \operatorname{div}(\sigma_k(x) \operatorname{div}(\sigma_k(x) \mu_s)) = \Delta \mu_s.$$

Therefore the Itô formulation of equation (4) is (8).

2.3 Extensions and variants

As we remarked in the Introduction, we chose to work under Hypothesis 1, since it leads to particularly simple and elegant equations and relations between Itô and Stratonovich formulations. However, all the results hold in more general cases, some of which we discuss here.

Assume $u, \sigma_k : [0, T] \times \mathbb{R}^d \rightarrow \mathbb{R}^d$, $k \in \mathbb{N}$, are measurable vector fields such that, for some constants $C, L > 0$

$$|u(t, x)|^2 + \sum_{k=1}^{\infty} |\sigma_k(t, x)|^2 \leq C(1 + |x|^2)$$

$$|u(t, x) - u(t, y)|^2 + \sum_{k=1}^{\infty} |\sigma_k(t, x) - \sigma_k(t, y)|^2 \leq L |x - y|^2$$

for all $x, y \in \mathbb{R}^d$ and all $t \in [0, T]$. Under these conditions, always with K Lipschitz continuous, consider the system of equations in Itô form

$$dX_t^{i,N} = \frac{1}{N} \sum_{j=1}^N K(X_t^{i,N} - X_t^{j,N}) dt + u(t, X_t^{i,N}) dt + \sum_{k=1}^{\infty} \sigma_k(t, X_t^{i,N}) dB_t^k \quad (11)$$

$i = 1, \dots, N.$

Set

$$Q_t^{\alpha\beta}(x, y) := \sum_{k=1}^{\infty} \sigma_k^{\alpha}(t, x) \sigma_k^{\beta}(t, y)$$

$$a^{\alpha\beta}(t, x) := Q_t^{\alpha\beta}(x, x).$$

All results of the present paper hold true in this case with the corresponding SPDE given by

$$d\mu_t + \operatorname{div}((b_{\mu_t} + u)\mu_t) dt + \sum_{k=1}^{\infty} \operatorname{div}(\sigma_k \mu_t) dB_t^k = \frac{1}{2} \sum_{\alpha, \beta=1}^d \partial_{\alpha} \partial_{\beta} (a^{\alpha\beta}(t, \cdot) \mu_t^N) dt \quad (12)$$

(to be interpreted in weak form similarly to Definition 11 below). The connection between these two equations can be seen informally in a few lines by applying Itô formula to $\phi(X_t^{i,N})$, with $\phi \in C_c^{\infty}(\mathbb{R}^d)$; the result is that S_t^N satisfies

$$d\langle S_t^N, \phi \rangle = \langle S_t^N, \nabla \phi \cdot (b_{\mu_t} + u) \rangle dt + \sum_{k=1}^{\infty} \langle S_t^N, \nabla \phi \cdot \sigma_k(t, \cdot) \rangle dB_t^k + \left\langle S_t^N, \frac{1}{2} \sum_{\alpha, \beta=1}^d a^{\alpha\beta}(t, \cdot) \partial_{\alpha} \partial_{\beta} \phi \right\rangle dt$$

which is the weak formulation of the SPDE (12) above.

Remark 7. Assuming a suitable differentiability of $\sigma_k(t, \cdot)$ in the t variable, we may rewrite the SPDE (12) in Stratonovich form. We keep this remark at heuristic level, to avoid unnecessary details. As in the previous Section, the Stratonovich integral $\int_0^t \operatorname{div}(\sigma_k(s, x) \mu_s) \circ dB_s^k$ is equal to the Itô integral $\int_0^t \operatorname{div}(\sigma_k(s, x) \mu_s) dB_s^k$ plus the correction term

$$\frac{1}{2} [\operatorname{div}(\sigma_k(\cdot, x) \mu_{\cdot}), B^k]_t. \quad (13)$$

Now, $\sigma_k(t, x) \mu_t$ formally satisfies the identity (by Itô formula)

$$d(\sigma_k(t, x) \mu_t) = \frac{\partial \sigma_k}{\partial t}(t, x) \mu_t dt + \sigma_k(t, x) d\mu_t$$

hence only the term

$$-\sigma_k(t, x) \sum_{k'=1}^{\infty} \operatorname{div}(\sigma_{k'}(t, x) \mu_t) dB_t^{k'}$$

contributes to the quadratic covariation (13), which is thus equal (as in the previous Section) to

$$-\frac{1}{2} \int_0^t \operatorname{div}(\sigma_k(s, x) \operatorname{div}(\sigma_k(s, x) \mu_s)) ds.$$

From identity (9), where now $Q^{\alpha\beta}(x, x)$ is replaced by $a^{\alpha\beta}(t, x)$, we get that μ_t satisfies (in weak form) the Stratonovich equation

$$d\mu_t = -\operatorname{div}((b_{\mu_t} + u)\mu_t) dt - \sum_{k=1}^{\infty} \operatorname{div}(\sigma_k(t, \cdot) \mu_t) \circ dB_t^k + \mathcal{D}(t, \cdot) \mu_t dt \quad (14)$$

where the first order differential operator $\mathcal{D}(t, x)$ is given by

$$\mathcal{D}f := \frac{1}{2} \operatorname{div} \left(\sum_{k=1}^{\infty} D\sigma_k \cdot \sigma_k f \right).$$

Remark 8. The Stratonovich reformulation (14) reveals that the true nature of the SPDE (12) is not parabolic but of a first order equation, informally speaking of hyperbolic type.

If we start from the beginning with the Stratonovich equation

$$dX_t^{i,N} = \frac{1}{N} \sum_{j=1}^N K \left(X_t^{i,N} - X_t^{j,N} \right) dt + u \left(t, X_t^{i,N} \right) dt + \sum_{k=1}^{\infty} \sigma_k \left(t, X_t^{i,N} \right) \circ dB_t^k$$

in place of (11), we may rewrite it in the Itô form

$$\begin{aligned} dX_t^{i,N} &= \frac{1}{N} \sum_{j=1}^N K \left(X_t^{i,N} - X_t^{j,N} \right) dt + u \left(t, X_t^{i,N} \right) dt \\ &\quad + \sum_{k=1}^{\infty} \sigma_k \left(t, X_t^{i,N} \right) dB_t^k + \frac{1}{2} \sum_{k=1}^{\infty} (D\sigma_k \cdot \sigma_k) \left(t, X_t^{i,N} \right) dt \end{aligned}$$

where $(D\sigma_k \cdot \sigma_k)^\alpha = \sum_{\beta=1}^d \partial_\beta \sigma_k^\alpha \sigma_k^\beta$. This is the case, because the correction term of the α -component is

$$\frac{1}{2} \sum_{k=1}^{\infty} d \left[\sigma_k^\alpha (\cdot, X_t^{i,N}), B_t^k \right]_t = \frac{1}{2} \sum_{k=1}^{\infty} \nabla \sigma_k^\alpha \left(t, X_t^{i,N} \right) \cdot \sigma_k \left(t, X_t^{i,N} \right) dt$$

since, under suitable differentiability assumptions on σ_k , we may apply Itô formula to $\sigma_k^\alpha \left(t, X_t^{i,N} \right)$ and see that for the quadratic covariation $\left[\sigma_k^\alpha (\cdot, X_t^{i,N}), B_t^k \right]_t$ only the following term (part of $\nabla \sigma_k^\alpha \left(t, X_t^{i,N} \right) \cdot dX_t^{i,N}$) matters:

$$\nabla \sigma_k^\alpha \left(t, X_t^{i,N} \right) \cdot \sum_{k'=1}^{\infty} \sigma_{k'} \left(t, X_t^{i,N} \right) dB_t^{k'}.$$

Thus we see that under appropriate regularity and summability (in k) properties on σ_k , we may transform the Stratonovich equation into the Itô one (11) and apply the previous result. The additional drift

$$\frac{1}{2} \sum_{k=1}^{\infty} (D\sigma_k \cdot \sigma_k) (t, x) \tag{15}$$

appears in the Itô formulation.

Finally, we have seen that two annoying correction terms appear in the computations above, namely $\mathcal{D}(t, \cdot) \mu_t$ in the SPDE (14) and the additional drift (15). Both are related to passages from Itô to Stratonovich forms. Both of them are equal to zero if we assume

$$\sum_{k=1}^{\infty} D\sigma_k \cdot \sigma_k = 0.$$

Similarly to (10), this can be rewritten as

$$\sum_{\beta=1}^d \partial_\beta a^{\alpha\beta} (t, x) - \sum_{k=1}^{\infty} \sigma_k^\alpha \operatorname{div} \sigma_k = 0.$$

A sufficient condition thus is the pair of assumptions

$$\begin{aligned} a^{\alpha\beta} (t, x) &\text{ independent of } x \\ \operatorname{div} \sigma_k &= 0 \text{ for every } k \end{aligned}$$

which are part of Hypothesis 1.

2.4 Some definitions

Recall the definition of the empirical measure $S_t^N := \frac{1}{N} \sum_{i=1}^N \delta_{X_t^{i,N}}$, which can be used, as we did in the introduction, to rewrite the drift coefficient as $b_{S_t^N}(x) = K * S_t^N(x) = \frac{1}{N} \sum_{j=1}^N K(x - X_t^{j,N})$. We can thus write equation (7), for $i = 1, \dots, N$, as

$$dX_t^{i,N} = b_{S_t^N}(X_t^{i,N})dt + \sum_{k=1}^{\infty} \sigma_k(X_t^{i,N})dB_t^k$$

If we take a test function $\phi \in C_b^2(\mathbb{R}^d)$ and we apply Itô's formula, from the assumptions on Q it follows, for $i = 1, \dots, N$,

$$d\phi(X_t^{i,N}) = \left[\nabla \phi(X_t^{i,N}) \cdot b_{S_t^N}(X_t^{i,N}) + \frac{1}{2} \Delta \phi(X_t^{i,N}) \right] dt + \sum_{k=1}^{\infty} \nabla \phi(X_t^{i,N}) \cdot \sigma_k(X_t^{i,N}) dB_t^k$$

which becomes, adding over N and dividing by N

$$\langle S_t^N, \phi \rangle = \left[\langle S_t^N, \nabla \phi \cdot b_{S_t^N} \rangle + \frac{1}{2} \langle S_t^N, \Delta \phi \rangle \right] dt + \sum_{k=1}^{\infty} \langle S_t^N, \nabla \phi \cdot \sigma_k \rangle dB_t^k.$$

Hence S_t^N is a measure-valued solution of equation (4), in the sense of Definition 11 below.

We define now the space over which we will study equation (4).

Definition 9. • $(\mathcal{P}_1(\mathbb{R}^d), W_1)$ is the space of probability measures μ_0 on \mathbb{R}^d with finite first moment, i.e.,

$$\|\mu_0\| := \int_{\mathbb{R}^d} d\mu_0 = 1, \quad M_1(\mu_0) := \int_{\mathbb{R}^d} |x| d\mu_0(x) < \infty$$

endowed with the 1-Wasserstein metric defined as

$$W_1(\nu_0, \mu_0) = \inf_{m \in \Gamma(\mu_0, \nu_0)} \int_{\mathbb{R}^{2d}} |x - y| m(dx, dy), \quad \mu_0, \nu_0 \in \mathcal{P}_1(\mathbb{R}^d)$$

Here $\Gamma(\mu_0, \nu_0)$ is the set of the finite measures on \mathbb{R}^{2d} with first and second marginals equal respectively to μ_0 and ν_0 , namely

$$\Gamma(\mu_0, \nu_0) = \{m \in \mathcal{P}_1(\mathbb{R}^{2d}) : m(A \times \mathbb{R}^d) = \mu_0(A), m(\mathbb{R}^d \times A) = \nu_0(A), \forall A \in \mathcal{B}(\mathbb{R}^d)\}$$

- \mathcal{S} will be the space of the stochastic processes taking values on $(\mathcal{P}_1(\mathbb{R}^d), W_1)$,

$$\mu : [0, T] \times \Omega \rightarrow \mathcal{P}_1(\mathbb{R}^d)$$

such that $\mathbb{E} \left[\sup_{t \in [0, T]} \int_{\mathbb{R}^d} |x| d\mu_t(x) \right] < \infty$ and $\langle \mu_t, \phi \rangle$ is \mathcal{F}_t -adapted for every test function $\phi \in C_b^\infty(\mathbb{R}^d)$. We endow \mathcal{S} with the following distance

$$d_{\mathcal{S}}(\mu, \nu) := \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \right]$$

where $\mu = (\mu_t)_{t \in [0, T]}, \nu = (\nu_t)_{t \in [0, T]} \in \mathcal{S}$.

Remark 10. The metric space $(\mathcal{P}_1(\mathbb{R}^d), W_1)$ has been well studied in optimal transportation theory and extensive results on it can be found in the literature, (see, e.g [1]). In particular this space is complete and separable (Proposition 7.1.5 of [1]). Hence, follows from standard arguments that $(\mathcal{S}, d_{\mathcal{S}})$ is also a complete metric space.

Hypothesis 2. Concerning the initial condition $\mu_0 : \Omega \rightarrow \mathcal{P}_1(\mathbb{R}^d)$ of equation (4) we shall always assume that

- i) μ_0 is \mathcal{F}_0 -measurable;
- ii) $\mathbb{E} \left[\int_{\mathbb{R}^d} |x| d\mu_0(x) \right] < \infty$.

For every μ_0 that satisfies the previous Hypotesis, we call \mathcal{S}_{μ_0} the set of $\mu \in \mathcal{S}$ such that $\mu|_{t=0} = \mu_0$.

Definition 11. A family $\{\mu_t(\omega); t \geq 0, \omega \in \Omega\}$ of random probability measures taking value in $\mathcal{P}_1(\mathbb{R}^d)$ is a measure-valued solution of equation (4) if

- i) for all $\phi \in C_b(\mathbb{R}^d)$, $\langle \mu_t, \phi \rangle$ is an adapted process with a continuous version,
- ii) for all $\phi \in C_b^2(\mathbb{R}^d)$

$$\begin{aligned} \langle \mu_t, \phi \rangle &= \langle \mu_0, \phi \rangle + \int_0^t \langle \mu_s, b_{\mu_s} \cdot \nabla \phi \rangle ds + \frac{1}{2} \int_0^t \langle \mu_s, \Delta \phi \rangle ds \\ &\quad + \sum_{k=1}^{\infty} \int_0^t \langle \mu_s, \sigma_k \cdot \nabla \phi \rangle dB_s^k. \end{aligned}$$

Remark 12. Notice that the infinite sum in the previous equation converges under our assumptions. Indeed, if $\phi \in C_b^2(\mathbb{R}^d)$, it holds, by Itô isometry and Jensen inequality,

$$\mathbb{E} \left[\left| \sum_{k=1}^{\infty} \int_0^t \langle \mu_s, \sigma_k \cdot \nabla \phi \rangle dB_s^k \right|^2 \right] = \mathbb{E} \left[\sum_{k=1}^{\infty} \int_0^t \langle \mu_s, \sigma_k \cdot \nabla \phi \rangle^2 ds \right] \leq \mathbb{E} \left[\sum_{k=1}^{\infty} \int_0^t \langle \mu_s, |\sigma_k \cdot \nabla \phi|^2 \rangle ds \right]$$

Now, by the assumptions on σ_k , we have

$$\sum_{k=1}^{\infty} |\sigma_k(x) \cdot \nabla \phi(x)|^2 \leq \sum_{k=1}^{\infty} |\nabla \phi(x)|^2 |\sigma_k(x)|^2 = |\nabla \phi(x)|^2 \sum_{k=1}^{\infty} |\sigma_k(x)|^2 \leq C |\nabla \phi(x)|^2 < +\infty$$

3 Well Posedness of the stochastic PDE

In this chapter we study the wellposedness of equation (4) and thus we prove the following

Theorem 13. Let $T \geq 0$ and $\mu_0 : \Omega \rightarrow \mathcal{P}_1(\mathbb{R}^d)$ be as in Hypotesis 2. There exists a unique solution $\mu = (\mu_t)_{t \in [0, T]}$ of equation (4) in the sense of Definition 11 starting from μ_0 and defined up to time T , that can be seen as the only fixed point of the operator (27) defined below.

We have already seen that the empirical measure S_t^N defined in (3) satisfies in the distributional sense (4) for every test function ϕ , moreover it is a probability measure with finite first moment and the process

$$\langle S_t^N, \phi \rangle = \frac{1}{N} \sum_{i=1}^N \phi(X_t^{i, N})$$

is \mathcal{F}_t -adapted. This is true since the processes $X_t^{i, N}$ are solutions of the SDE (7) and hence are adapted and continuous. Hence the empirical measure S_t^N satisfies (4) in the sense of definition 11.

3.1 Stochastic Liouville Equation

In order to investigate the solutions of equation (4) we first want to study what happens when the drift coefficient does not depend on the solution but it is instead a priori defined (but random). We hence consider the following stochastic differential equation,

$$\begin{aligned} dX_t &= b(t, X_t)dt + \sum_k^{\infty} \sigma_k(X_t)dB_t^k \\ X_0 &= x \in \mathbb{R}^d \end{aligned} \tag{16}$$

where the σ_k 's are defined as before. Here $b = b(t, x, \omega)$ is an \mathcal{F}_t -adapted process, continuous in (t, x) , which satisfies:

- b Lipschitz continuous in x uniformly in (t, ω) , with Lipschitz constant L_b , non depending on ω and t , i.e.

$$|b(t, x, \omega) - b(t, y, \omega)| \leq L_b |x - y| \quad \forall x, y \in \mathbb{R}^d, \quad \forall t \in \mathbb{R}, \quad \mathbb{P} - \text{a.s.}$$

- For every fixed w , b has linear growth in x uniformly t , i.e.

$$|b(t, x, \omega)| \leq c_1 |x| + c_2(\omega) \quad \forall x \in \mathbb{R}^d, \quad \forall t \in \mathbb{R}, \quad \text{for } \mathbb{P}\text{-a.e. } \omega$$

where $c_1 \in \mathbb{R}$ and $c_2(\omega)$ is a random variable such that $\mathbb{E}[|c_2(\omega)|] < \infty$.

By classical results on SDEs (see eg [12]) this equation admits a unique solution $X_t = X(t, x, \omega)$ which is continuous in time. Moreover, taking into account the following lemma, it follows from Kolmogorov continuity theorem that there exists a modification of $X(t, x)$ which is continuous in x . It is also jointly continuous in (t, x) by Kolmogorov theorem for processes taking values in Banach spaces, precisely in the space $C([0, T]; \mathbb{R}^d)$. This results on continuity of the stochastic flow of equation (16) can be find in the literature, like in [12]. However we want to stress in the following the dependence on the different parameters and outline more explicitly the constants.

We define now some constants depending on the coefficients b and σ_k of the problem, which we will use in the following results. For a fixed real number $p \geq 1$ we call C_p the constat which appears in the Burkholder Davis Gundy Theorem. Moreover, for $t > 0$ and $p \geq 1$, we define

$$C(p, t) := C_p T^{\frac{1}{2p}} L_\sigma + T^{\frac{1}{p}} L_b \quad (17)$$

Finally, for a fixed $T > 0$, let $n \in \mathbb{N}$ be the minimum such that $C(p, (T/n)) < 1$, so that we can define

$$C_{p,T} := (1 - C(p, (T/n)))^{-np} \quad (18)$$

From our choice of $n \in \mathbb{N}$ this last constant is well defined and depending only on T, p and the coefficients of problem (16).

Lemma 14. *Let $p \geq 1$, $T \geq 0$ and let $X(t, x)$ be a solution of equation (16) up to time T . Then*

$$\mathbb{E} \left[\sup_{t \in [0, T]} |X(t, x) - X(t, x')|^p \middle| \mathcal{F}_0 \right] \leq C_{p,T} |x - x'|^p \quad (19)$$

where the constant $C_{p,T}$ is defined in (18).

Proof. Let $n \in \mathbb{N}$ be the minimum such that $C(p, (T/n)) < 1$, where $C(., .)$ is defined in (17). Now we divide the temporal interval $[0, T]$ in n subintervals. We set $X^{(0)}(t, x) = x$ and we call $X^{(m)}$, for $m = 1, \dots, n$, the solution to

$$\begin{aligned} dX_t &= b(t, X_t)dt + \sum_k^\infty \sigma_k(X_t)dB_t^k \\ X_{\frac{m-1}{n}T} &= X^{(m-1)}(\frac{m-1}{n}T, x) \end{aligned}$$

on the interval $[\frac{m-1}{n}T, \frac{m}{n}T]$. We prove by induction that, for every $m = 1, \dots, n$,

$$\mathbb{E} \left[\sup_{t \in [\frac{m-1}{n}T, \frac{m}{n}T]} |X^{(m)}(t, x) - X^{(m)}(t, x')|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \leq \frac{|x - x'|}{(1 - C(p, (T/n)))^m} \quad (20)$$

It follows from the uniqueness of solution of the stochastic differential equations that the solution X_t of equation (16) coincides on each interval $[\frac{m-1}{n}T, \frac{m}{n}T]$ with the process $X_t^{(m)}$. The thesis follows noting that the worst constant in (20) appears when $m = n$ and it coincides with $C_{p,T}$.

Step 1. Now we prove (20) for $m = 1$. By a triangular inequality we get

$$\begin{aligned} & \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| X^{(1)}(t, x) - X^{(1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \leq |x - x'| \\ & + \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t b(s, X^{(1)}(s, x)) - b(s, X^{(1)}(s, x')) ds \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & + \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t \sum_k \sigma_k(X^{(1)}(s, x)) - \sigma_k(X^{(1)}(s, x')) dB_s^k \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \end{aligned}$$

In order to estimate this, we first notice that, by the Lipschitz continuity of b one can get

$$\mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t b(s, X^{(1)}(s, x)) - b(s, X^{(1)}(s, x')) ds \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \leq ((T/n))^{\frac{1}{p}} L_b \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| X^{(1)}(t, x) - X^{(1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}}$$

Now, using the conditional Burkholder Davis Gundy inequality (Proposition 27), we obtain

$$\begin{aligned} & \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t \sum_k \sigma_k(X^{(1)}(s, x)) - \sigma_k(X^{(1)}(s, x')) dB_s^k \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & \leq C_p \mathbb{E} \left[\left(\int_0^{(T/n)} \sum_k \left| \sigma_k(X^{(1)}(s, x)) - \sigma_k(X^{(1)}(s, x')) \right|^2 ds \right)^{\frac{p}{2}} \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & \leq C_p ((T/n))^{\frac{1}{2p}} L_\sigma \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| X^{(1)}(t, x) - X^{(1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \end{aligned}$$

We have hence proved the base step of the induction.

Step 2 Now we suppose (20) true for m and we prove it for $m + 1$. First, thanks to a triangular inequality we obtain

$$\begin{aligned} & \mathbb{E} \left[\sup_{t \in [\frac{m}{n}T, \frac{m+1}{n}T]} \left| X^{(m+1)}(t, x) - X^{(m+1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & \leq \mathbb{E} \left[\left| X^{(m)}\left(\frac{m}{n}T, x\right) - X^{(m)}\left(\frac{m}{n}T, x'\right) \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & + \mathbb{E} \left[\sup_{t \in [\frac{m}{n}T, \frac{m+1}{n}T]} \left| \int_{\frac{m}{n}T}^t b(s, X^{(m+1)}(s, x)) - b(s, X^{(m+1)}(s, x')) ds \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \\ & + \mathbb{E} \left[\sup_{t \in [\frac{m}{n}T, \frac{m+1}{n}T]} \left| \int_{\frac{m}{n}T}^t \sum_k \sigma_k(X^{(m+1)}(s, x)) - \sigma_k(X^{(m+1)}(s, x')) dB_s^k \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}}. \end{aligned}$$

Now, as in Step 1, we use the Lipschitz property of b and σ_k and Lemma 27 to get

$$\mathbb{E} \left[\sup_{t \in [\frac{m}{n}T, \frac{m+1}{n}T]} \left| X^{(m+1)}(t, x) - X^{(m+1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \leq \frac{\mathbb{E} \left[\left| X^{(m)}\left(\frac{m}{n}T, x\right) - X^{(m)}\left(\frac{m}{n}T, x'\right) \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}}}{(1 - C(p, (T/n)))^p}$$

Now estimate the right hand side using (20) for m and we conclude this last step,

$$\mathbb{E} \left[\sup_{t \in [\frac{m}{n}T, \frac{m+1}{n}T]} \left| X^{(m+1)}(t, x) - X^{(m+1)}(t, x') \right|^p \middle| \mathcal{F}_0 \right]^{\frac{1}{p}} \leq \frac{|x - x'|}{(1 - C(p, (T/n)))^m} \frac{1}{(1 - C(p, (T/n)))}$$

□

Using the continuous version in x of the solution of equation (16) we are going to define a solution for equation (4) in the case in which the drift coefficient is fixed. This is shown in the following proposition. The push forward described in the next statement has to be understood ω -wise: for a.e. ω and for each $t \in [0, T]$, we take the initial measure $\mu_0(\omega) = \mu_0(\omega, dx)$ and we consider its image measure (or push forward) under the continuous map $x \mapsto X(t, x, \omega)$, denoted by $\mu_t(\omega)$ or $\mu_t(\omega, dx)$.

Proposition 15. *Given μ_0 which satisfies Hypotesis 2, the push forward of μ_0 with respect to the solution of (16) namely*

$$\mu_t(\omega) = X(t, \cdot, \omega)_\# \mu_0(\omega)$$

solves the following equation in the sense of Definition 11.

$$\begin{cases} d\mu_t = -\operatorname{div}(b\mu_t) dt - \sum_{k=0}^{\infty} \operatorname{div}(\sigma_k \mu_t) dB_t^k + \frac{1}{2} \Delta \mu_t \\ \mu_t|_{t=0} = \mu_0 \end{cases}$$

Proof. First notice that $\mu \in \mathcal{S}$. By definition, for every $t \in [0, T]$ and \mathbb{P} -a.s., μ_t is a finite and positive measure. We show that the first moment of μ_t is finite,

$$\begin{aligned} \mathbb{E} \left[\int_{\mathbb{R}^d} |x| d\mu_t(x) \right] &= \mathbb{E} \left[\int_{\mathbb{R}^d} |X_t| d\mu_0(x) \right] \\ &\leq \mathbb{E} \left[\int_{\mathbb{R}^d} |x| d\mu_0(x) \right] \end{aligned} \quad (21)$$

$$+ \mathbb{E} \left[\int_{\mathbb{R}^d} \int_0^t |b(X(s, x))| ds d\mu_0(x) \right] \quad (22)$$

$$+ \mathbb{E} \left[\int_{\mathbb{R}^d} \left| \int_0^t \sum_k \sigma_k(X(s, x)) dB_s^k \right| d\mu_0(x) \right] \quad (23)$$

It follows from the choice of μ_0 that (21) is finite. We can bound (22) if we notice that the Lipschitz continuity assumption on b implies $|b(x)| \leq 1 + |x|$, which gives

$$\mathbb{E} \left[\int_{\mathbb{R}^d} \int_0^t |b(X(s, x))| ds d\mu_0(x) \right] \leq CT + C \int_0^t \mathbb{E} \left[\int_{\mathbb{R}^d} |x| d\mu_s(x) \right] ds \quad (24)$$

In order to bound (23) we use Proposition 28 and Proposition 27 and we do the following

$$\begin{aligned} \mathbb{E} \left[\mathbb{E} \left[\int_{\mathbb{R}^d} \left| \int_0^t \sum_{k=0}^{\infty} \sigma_k(X(s, x)) dB_s^k \right| d\mu_0(x) \middle| \mathcal{F}_0 \right] \right] &= \mathbb{E} \left[\int_{\mathbb{R}^d} \mathbb{E} \left[\left| \int_0^t \sum_{k=0}^{\infty} \sigma_k(X(s, x)) dB_s^k \right| \middle| \mathcal{F}_0 \right] d\mu_0(x) \right] \\ &\leq C \mathbb{E} \left[\int_{\mathbb{R}^d} \mathbb{E} \left[\int_0^t \sum_{k=0}^{\infty} |\sigma_k(X(s, x))|^2 ds \middle| \mathcal{F}_0 \right]^{\frac{1}{2}} d\mu_0(x) \right] \\ &\leq C\sqrt{T} \end{aligned} \quad (25)$$

Here we used $\sum_{k=0}^{\infty} |\sigma_k(X(s, x))|^2 < +\infty$. Taking in to account (24) and (25) we can apply Gronwall Lemma to deduce that the first moment of μ_t is finite for every t . Let us stress a detail. In order to apply Proposition 28 of the Appendix, we need to know that the random field (t here is fixed)

$$f(x) = \int_0^t \sum_{k=0}^{\infty} \sigma_k(X(s, x)) dB_s^k$$

is continuous, or it has a continuous modification. This is true because, by BDG inequality,

$$\begin{aligned}
E[|f(x) - f(y)|^p] &= E\left[\left|\int_0^t \sum_{k=0}^{\infty} (\sigma_k(X(s, x)) - \sigma_k(X(s, y))) dB_s^k\right|^p\right] \\
&\leq C_p E\left[\left(\int_0^t \sum_{k=0}^{\infty} |\sigma_k(X(s, x)) - \sigma_k(X(s, y))|^2 ds\right)^{p/2}\right] \\
&\leq C_p L_\sigma^p E\left[\left(\int_0^t |X(s, x) - X(s, y)|^2 ds\right)^{p/2}\right] \\
&\leq C_{p,T} C_p L_\sigma^p T |x - y|^p.
\end{aligned}$$

This last inequality follows from Lemma 14. Thus for $p > d$ we may apply Kolmogorov regularity theorem and deduce that f has a continuous version.

We show now that μ_t satisfies the conditions of Definition 11:

- (i) to prove that $\langle \mu_t, \phi \rangle$ is continuous and adapted, it is sufficient to notice that

$$\langle \mu_t, \phi \rangle = \int_{\mathbb{R}^d} \phi(X(t, x)) \mu_0(dx).$$

- (ii) Let $\phi \in C_b^2(\mathbb{R}^d)$, we apply Itô's formula

$$d\phi(X_t) = \nabla\phi(X_t) \cdot dX_t + \frac{1}{2} \sum_k \sum_{i,j=1}^d \partial_{i,j}^2 \phi(X_t) \sigma_k^i(X_t) \sigma_k^j(X_t) dt$$

Under the homogeneity assumption over σ_k , we obtain the following

$$d\phi(X_t) = \left[\nabla\phi(X_t) \cdot b(X_t) + \frac{1}{2} \Delta\phi(X_t) \right] dt + \sum_k \nabla\phi(X_t) \sigma_k(X_t) dB_t^k$$

Integrating now over μ_0 we get

$$d\langle \mu_t, \phi \rangle = \left[\langle \mu_t, \nabla\phi \cdot b \rangle + \frac{1}{2} \langle \mu_t, \Delta\phi \rangle \right] dt + \sum_k \int_{\mathbb{R}^d} \nabla\phi(X_t) \sigma_k(X_t) dB_t^k d\mu_0$$

Using the stochastic Fubini's Theorem, we interchange the stochastic integral and the integral in μ_0 and we obtain the desired equation. \square

3.2 The Contraction Mapping

In this section we will construct a solution of equation (4) by mean of a fixed point argument. Given $\mu_0 : \Omega \rightarrow \mathcal{P}_1(\mathbb{R}^d)$ as in Hypotesis 2 we define now an operator $\Phi_{\mu_0} : \mathcal{S} \rightarrow \mathcal{S}$. In Theorem 17 we prove that it is a contraction and we see that his unique fixed point is a solution to (4).

Let $\mu = (\mu_t)_{t \in [0, T]} \in \mathcal{S}$. We define the following as the convolution between μ_t and K ,

$$b_\mu(t, x, \omega) := \int_{\mathbb{R}^d} K(x - y) \mu_t(\omega, dy).$$

Notice that $b_\mu(t, \cdot, \omega)$ is Lipschitz continuous with Lipschitz constant L_K , which is the Lipschitz constant of K and does not depend on t and ω . Moreover, since $|K(x)| \leq L_K(K(0) + |x|)$,

$$\begin{aligned}
|b_\mu(t, 0, \omega)| &\leq \int_{\mathbb{R}^d} |K(-y)| \mu_t(\omega, dy) \leq L_K \int_{\mathbb{R}^d} (K(0) + |y|) \mu_t(\omega, dy) \\
&\leq L_K K(0) + L_K \int_{\mathbb{R}^d} |x| \mu_t(\omega, dx)
\end{aligned}$$

and the random variable $\int_{\mathbb{R}^d} |x| \mu_t(\omega, dx)$ is integrable. Hence b_μ satisfies the assumptions required in Section 3 to have strong existence and uniqueness of solutions. Let now X_t^μ be the solution to equation (16) with drift coefficient b_μ , namely

$$\begin{aligned} dX_t &= b_\mu(X_t)dt + \sum_k \sigma_k(X_t)dB_t^k \\ X_0 &= x \end{aligned} \quad (26)$$

Let $X^\mu(t, x, \omega)$ be a modification of X_t^μ continuous in x . We define, for every t ,

$$(\Phi_{\mu_0}\mu)_t(\omega) := X^\mu(t, \cdot, \omega)_{\#}\mu_0(\omega) \quad \omega\text{-a.s.} \quad (27)$$

Remark 16. Notice that the range of Φ_{μ_0} is included in \mathcal{S}_{μ_0} and that $\Phi_{\mu_0}\mu$ is a solution of equation (4) in the sens of Definition 11, thanks to Proposition 15.

From Lemma 19 and Proposition 15 we deduce the following Theorem, which is the main result of this Section.

Theorem 17. *Given $T > 0$, the operator Φ_{μ_0} has a unique fixed point $\mu = \{\mu_t\}_{t \in [0, T]}$ in \mathcal{S}_{μ_0} . This fixed point is a solution of equation (4).*

Proof. From Lemma 19 we have

$$d_S(\Phi_{\mu_0}\mu, \Phi_{\mu_0}\nu) \leq \gamma_T d_S(\mu, \nu) \quad \forall \mu, \nu \in \mathcal{S}$$

where γ_T is defined in (28) as $\gamma_T := L_K T C_{1, T}$. Hence there exists a time t^* up to which the operator Φ_{μ_0} is a contraction, thus it has a unique fixed point $\mu = (\mu_t)_{t \in [0, t^*]}$. It follows from Proposition 15 that μ is a solution, in the sense of Definition 11, to equation (4) on the interval $[0, t^*]$, starting from μ_0 . We can repeat this method on the interval $[t^*, 2t^*]$ with initial condition μ_{t^*} , and iterate it up to any finite time T because t^* depends only on the Lipschitz constants of the coefficients, and not on the initial condition. In this way we have shown that we can construct a solution μ on the interval $[0, T]$ which is a fixed point for the operator $\Phi_{\mu_{nt^*}}$ on the interval $[nt^*, (n+1)t^*]$, for every $n \in \mathbb{N}$ such that $nt^* < T$. Moreover we can prove that any two fixed point μ, ν of the map Φ_{μ_0} on the interval $[0, T]$ coincide. Indeed if $t_0 \in [0, T]$ is the largest time such that $\mu = \nu$, one proves $t_0 = T$ by contradiction, by applying the contraction argument on $[t_0, t_0 + \delta]$ for a suitable $\delta > 0$, if $t_0 < T$. \square

Lemma 18. *Set $T > 0$. Let $\mu = \{\mu_t\}_{t \geq 0}, \nu = \{\nu_t\}_{t \geq 0} \in \mathcal{S}$ and let X^μ, X^ν be the solutions of equation (26) with drift coefficients b_μ and b_ν respectively. The following holds true*

$$\mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] \leq \gamma_T \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right]$$

where

$$\gamma_T := L_K T C_{1, T}. \quad (28)$$

The constant $C_{1, T}$ is defined in (18).

Proof. Given $T > 0$, we call n the smallest positive integer such that $C(1, (T/n)) < 1$ (see (17)). We split the interval $[0, T]$ in n sub intervals, namely $[\frac{m-1}{n}T, \frac{m}{n}T]$, for $m \leq n$. We will give the proof by induction over m .

First we prove our claim on the interval $[0, (T/n)]$. We start our estimation by giving bounds for the drift and the noise of equation (26). It holds, \mathbb{P} -a.s.,

$$\begin{aligned} \int_0^t |b_\mu(s, X^\mu(s, x)) - b_\nu(s, X^\nu(s, x))| ds &\leq \int_0^t |b_\mu(s, X^\mu(s, x)) - b_\mu(s, X^\nu(s, x))| ds \\ &\quad + \int_0^t |b_\mu(s, X^\nu(s, x)) - b_\nu(s, X^\nu(s, x))| ds \\ &\leq L_K \int_0^t |X^\mu(s, x) - X^\nu(s, x)| ds + L_K \int_0^t W_1(\mu_s, \nu_s) ds \end{aligned} \quad (29)$$

Here we used that, for every $t \in [0, (T/n)]$, $x \in \mathbb{R}^d$ and \mathbb{P} -a.s.,

$$|b_\mu(t, x) - b_\nu(t, x)| \leq L_K W_1(\mu_t, \nu_t) \quad (30)$$

To prove this we apply first the definition of b_μ :

$$|b_\mu(t, x) - b_\nu(t, x)| = \left| \int_{\mathbb{R}^d} K(x - y) d\mu_t(y) - \int_{\mathbb{R}^d} K(x - y') d\nu_t(y') \right|$$

Given $\omega \in \Omega$ a.s. and $t \in [0, (T/n)]$ for every $m \in \Gamma(\mu_t(\omega), \nu_t(\omega))$ so we can rewrite the right hand side as follows and then apply the Lipschitz continuity of K to obtain, for \mathbb{P} -a.e. ω ,

$$\begin{aligned} |b_\mu(s, x) - b_\nu(s, x)| &= \left| \int_{\mathbb{R}^d \times \mathbb{R}^d} K(x - y) dm(y, y') - \int_{\mathbb{R}^d \times \mathbb{R}^d} K(x - y') dm(y, y') \right| \\ &\leq \int_{\mathbb{R}^d \times \mathbb{R}^d} |K(x - y) - K(x - y')| dm(y, y') \\ &\leq L_K \int_{\mathbb{R}^d \times \mathbb{R}^d} |y - y'| dm(y, y') \end{aligned}$$

Now (30) follows since m is arbitrary.

Using the conditional Burkholder-Davis-Gundy inequality (see Proposition 27) and the Lipschitz continuity of the noise, we can estimate the following,

$$\begin{aligned} &\mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t \sum_k \sigma_k(X^\mu(s, x)) - \sigma_k(X^\nu(s, x)) dB_s^k \right| \middle| \mathcal{F}_0 \right] \\ &\leq C_1 \mathbb{E} \left[\left(\int_0^{(T/n)} \sum_k (\sigma_k(X^\mu(s, x)) - \sigma_k(X^\nu(s, x)))^2 ds \right)^{\frac{1}{2}} \middle| \mathcal{F}_0 \right] \\ &\leq C_1 L_\sigma \mathbb{E} \left[\left(\int_0^{(T/n)} |X^\mu(t, x) - X^\nu(t, x)|^2 dt \right)^{\frac{1}{2}} \middle| \mathcal{F}_0 \right] \\ &\leq C_1 (T/n)^{\frac{1}{2}} L_\sigma \mathbb{E} \left[\left(\sup_{t \in [0, (T/n)]} |X^\mu(t, x) - X^\nu(t, x)|^2 \right)^{\frac{1}{2}} \middle| \mathcal{F}_0 \right] \\ &\leq C_1 (T/n)^{\frac{1}{2}} L_\sigma \mathbb{E} \left[\sup_{t \in [0, (T/n)]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] \end{aligned} \quad (31)$$

We now use (29) and (31) to estimate the following

$$\begin{aligned} \mathbb{E} \left[\sup_{t \in [0, (T/n)]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] &\leq \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \int_0^t |b_\mu(s, X^\mu(t, x)) - b_\nu(s, X^\nu(t, x))| ds \middle| \mathcal{F}_0 \right] \\ &\quad + \mathbb{E} \left[\sup_{t \in [0, (T/n)]} \left| \int_0^t \sum_k (\sigma_k(X^\mu(s, x)) - \sigma_k(X^\nu(s, x))) dB_s^k \right| \middle| \mathcal{F}_0 \right] \\ &\leq \left(L_K (T/n) + C_1 L_\sigma (T/n)^{\frac{1}{2}} \right) \mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(s, x) - X^\nu(s, x)| \middle| \mathcal{F}_0 \right] \\ &\quad + L_K (T/n) \mathbb{E} \left[\sup_{t \in [0, (T/n)]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right]. \end{aligned}$$

Hence

$$\mathbb{E} \left[\sup_{t \in [0, (T/n)]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] \leq \frac{1}{1 - C(1, (T/n))} L_K(T/n) \mathbb{E} \left[\sup_{t \in [0, (T/n)]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right]$$

where $C(1, (T/n))$ is defined in (18).

We now prove the inductive step. Suppose that for some $m - 1 \leq n$, it holds

$$\mathbb{E} \left[\sup_{t \in [\frac{m-2}{n}T, \frac{m-1}{n}T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] \leq \left(L_K(T/n) \sum_{i=1}^{m-1} \left(\frac{1}{1 - C(1, (T/n))} \right)^i \right) \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right] \quad (32)$$

we will prove the same for m . In the same way as in the first step, one can deduce

$$\mathbb{E} \left[\sup_{t \in [\frac{m-1}{n}T, \frac{m}{n}T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] \leq \mathbb{E} \left[|X^\mu((m-1)T/n, x) - X^\nu((m-1)T/n, x)| \middle| \mathcal{F}_0 \right] \quad (33)$$

$$+ \left(L_K(T/n) + C_1 L_\sigma(T/n)^{\frac{1}{2}} \right) \mathbb{E} \left[\sup_{t \in [\frac{m-1}{n}T, \frac{m}{n}T]} |X^\mu(s, x) - X^\nu(s, x)| \middle| \mathcal{F}_0 \right] \quad (34)$$

$$+ L_K(T/n) \mathbb{E} \left[\sup_{t \in [\frac{m-1}{n}T, \frac{m}{n}T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right] \quad (35)$$

Now we use the inductive hypothesis (32) to estimate (33). We put (34) on the left hand side and we note that the supremum in (35) is less than the supremum over the whole interval.

$$\begin{aligned} C_{1, (T/n)}^{-1} \mathbb{E} \left[\sup_{t \in [\frac{m-1}{n}T, \frac{m}{n}T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] &\leq \left(L_K T \sum_{i=1}^{(m-1)} \left(\frac{1}{1 - C(1, (T/n))} \right)^i \right) \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right] \\ &\quad + L_K(T/n) \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right] \\ &= L_K(T/n) \left(\sum_{i=1}^{(m-1)} \left(\frac{1}{1 - C(1, (T/n))} \right)^i + 1 \right) \mathbb{E} \left[\sup_{t \in [0, T]} W_1(\mu_t, \nu_t) \middle| \mathcal{F}_0 \right] \end{aligned}$$

So (32) is proved for m .

Finally, to obtain the constant of Lemma 16 notice that $\frac{1}{1 - C(1, (T/n))} > 1$, hence $\left(\frac{1}{1 - C(1, (T/n))} \right)^i \leq \left(\frac{1}{1 - C(1, (T/n))} \right)^n$ when $i \leq n$. Thus the constant in (32), in the case $m = n$, can be further estimate by

$$\left(L_K(T/n) \sum_{i=1}^n \left(\frac{1}{1 - C(1, (T/n))} \right)^i \right) \leq \left(L_K(T/n) \sum_{i=1}^n \left(\frac{1}{1 - C(1, (T/n))} \right)^i \right) \leq L_K(T/n) n \left(\frac{1}{1 - C(1, (T/n))} \right)^n.$$

This last term is exactly γ_T because of the definition of $C_{1, T}$ (see (18)).

□

Lemma 19. *For every $T > 0$, we have*

$$d_S(\Phi_{\mu_0} \mu, \Phi_{\mu_0} \nu) \leq \gamma_T d_S(\mu, \nu) \quad \forall \mu, \nu \in \mathcal{S}$$

where γ_T is defined in (28).

Proof. Let $\omega \in \Omega$ and $t \in [0, T]$ be fixed. The measure $m = (X^\mu(t, \cdot, \omega), X^\nu(t, \cdot, \omega))_{\#} \mu_0$ belongs to $\Gamma((\Phi_{\mu_0} \mu)_t(\omega), (\Phi_{\mu_0} \nu)_t(\omega))$. Indeed, for every $A \in \mathbb{R}^{2d}$, it holds $m(B) = \mu_0\{x \in \mathbb{R}^d : X^\mu(t, x, \omega), X^\nu(t, x, \omega) \in B\}$, which implies, for every $A \in \mathcal{B}(\mathbb{R}^d)$,

$$m(A \times \mathbb{R}^d) = \mu_0\{x \in \mathbb{R}^d : X^\mu(t, x, \omega) \in A\} = X^\mu(t, \cdot, \omega)_{\#} \mu_0(A) = (\Phi_{\mu_0} \mu)_t(\omega)(A).$$

In the same way $m(\mathbb{R}^d \times A) = (\Phi_{\mu_0}\nu)_t(\omega)(A)$. Thus, from the definition of the Wasserstein metric W_1 it is easy to see that

$$d_S(\Phi_{\mu_0}\mu, \Phi_{\mu_0}\nu) \leq \mathbb{E} \left[\sup_{t \in [0, T]} \int_{\mathbb{R}^d} |X^\mu(t, x) - X^\nu(t, x)| d\mu_0 \right].$$

From the \mathcal{F}_0 -measurability of the initial condition μ_0 and applying Proposition 28, we have the following

$$\mathbb{E} \left[\mathbb{E} \left[\sup_{t \in [0, T]} \int_{\mathbb{R}^d} |X^\mu(t, x) - X^\nu(t, x)| d\mu_0 \middle| \mathcal{F}_0 \right] \right] = \mathbb{E} \left[\int_{\mathbb{R}^d} \mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] d\mu_0 \right].$$

Now we conclude the proof applying Lemma 18 as follows,

$$d_S(\Phi_{\mu_0}\mu, \Phi_{\mu_0}\nu) \leq \mathbb{E} \left[\int_{\mathbb{R}^d} \mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(t, x) - X^\nu(t, x)| \middle| \mathcal{F}_0 \right] d\mu_0 \right] \leq \gamma_T d_S(\mu, \nu).$$

□

4 Convergence and Propagation of Chaos

In this Section we will show that the distance between two solutions of (4) can be estimated by the distance between the respective initial conditions. Since we have shown in Section 2 that the Empirical measure solves (4) with the appropriate initial condition, we will be able to deduce from 20 some results of propagation of chaos.

Last we will give a review on recent quantitative results that can be applied together with Theorem 20 to obtain a more explicit rate of convergence to approximate the solution of SPDE (4) with the solution of SDE (1).

Theorem 20. *Given $T > 0$, let $\mu_0, \nu_0 : \Omega \rightarrow \mathcal{P}_1(\mathbb{R}^d)$ be as in Hypotesis 2, and let $\mu \in \mathcal{S}_{\mu_0}$, $\nu \in \mathcal{S}_{\nu_0}$ be the respective solutions of equation (4) given by the contraction method described before, there exists a constant $\tilde{C}_T > 0$, such that*

$$d_S(\mu, \nu) \leq \tilde{C}_T \mathbb{E}[W_1(\mu_0, \nu_0)]$$

Proof. Given $T > 0$, we define

$$\tilde{C}_T := \left(\frac{1}{(1 - \gamma_{(T/n)}) (1 - C(1, (T/n)))} \right)^n$$

where $n \in \mathbb{N}$ is the smallest integer such that $\gamma_{(T/n)} = L_K T C_{1,T} < 1$, see (18) for the definition of $C_{1,T}$, and $C(1, (T/n)) < 1$, defined in (17). We will give the proof in the case when T is small enough such that $n = 1$ and we refer to the inductive procedure used in Lemma 14 for the general case. Notice that under this assumption

$$\tilde{C}_T := \frac{C_{1,T}}{1 - \gamma_T}$$

where $C_{1,T}$ is defined in (18).

Notice that, since $\|\mu_0\| = \|\nu_0\| = 1$, the Lipschitz constants of b_μ and b_ν are the same, L_K . Moreover, recalling the definition of the operator Φ_{μ_0} (resp. Φ_{ν_0}), it holds that its fixed point μ (resp. ν) can be written as $\mu_t = X^\mu(t, \cdot)_{\#} \mu_0$ (resp. $\nu_t = X^\nu(t, \cdot)_{\#} \nu_0$) where $X^\mu(t, x, \omega)$ (resp. $X^\nu(t, x, \omega)$) is a continuous version of the solution of equation (16) with drift coefficient b_μ (resp. b_ν). Let now ω be fixed. Notice that the infimum in the definition of the Wasserstein metric is indeed a minimum (see [1], Chapter 6), i.e., there exists a measure $m(\omega) \in \Gamma(\mu_0(\omega), \nu_0(\omega))$ such that

$$\int_{\mathbb{R}^d \times \mathbb{R}^d} |x - x'| m(\omega, dx, dx') = W_1(\nu_0(\omega), \mu_0(\omega)). \quad (36)$$

Moreover, the function $\omega \mapsto m(\omega)$ is \mathcal{F}_0 -measurable. Indeed, for every couple of measures $(\mu, \nu) \in \mathcal{P}_1 \times \mathcal{P}_1$ we can construct a measurable map $(\mu, \nu) \mapsto m \in \Gamma_0(\mu, \nu)$ using Proposition 29 in the Appendix, and then

we can see that the function $\omega \mapsto (\mu_0(\omega), \nu_0(\omega)) \mapsto m(\omega)$ is \mathcal{F}_0 -measurable since it is a composition of measurable functions. If we define $m_t(\omega) = (X^\mu(t, \cdot, \omega), X^\nu(t, \cdot, \omega))_\# m(\omega)$, we get $m_t \in \Gamma((\Phi_{\mu_0}\mu)_t, (\Phi_{\nu_0}\nu)_t)$.

As a particular case of Lemma 14, we have that

$$\mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(t, x) - X^\mu(t, x')| \middle| \mathcal{F}_0 \right] \leq C_{1, T} |x - x'| \quad (37)$$

where $x, x' \in \mathbb{R}^d$ are two initial condition for equation (26).

In the following estimates we use the definition of the Wasserstein metric, the definition of m_t , Proposition 28, inequality (37) and identity (36),

$$\begin{aligned} \mathbb{E} \left[\sup_{t \in [0, T]} W_1((\Phi_{\mu_0}\mu)_t, (\Phi_{\nu_0}\nu)_t) \right] &\leq \mathbb{E} \left[\sup_{t \in [0, T]} \int_{\mathbb{R}^{2d}} |x - x'| dm_t(x, x') \right] \\ &= \mathbb{E} \left[\mathbb{E} \left[\sup_{t \in [0, T]} \int_{\mathbb{R}^{2d}} |X^\mu(t, x) - X^\mu(t, x')| dm(x, x') \middle| \mathcal{F}_0 \right] \right] \\ &\leq \mathbb{E} \left[\int_{\mathbb{R}^{2d}} \mathbb{E} \left[\sup_{t \in [0, T]} |X^\mu(t, x) - X^\mu(t, x')| \middle| \mathcal{F}_0 \right] dm(x, x') \right] \\ &\leq \mathbb{E} \left[\int_{\mathbb{R}^{2d}} C_{1, T} |x - x'| dm(x, x') \right] \\ &= C_{1, T} \mathbb{E}[W_1(\mu_0, \nu_0)]. \end{aligned} \quad (38)$$

Using now the definition of the operators $\Phi_{\mu_0}, \Phi_{\nu_0}$ and a triangular inequality we obtain

$$\begin{aligned} d_S(\mu, \nu) &= d_S(\Phi_{\mu_0}\mu, \Phi_{\nu_0}\nu) \\ &\leq d_S(\Phi_{\mu_0}\mu, \Phi_{\nu_0}\mu) + d_S(\Phi_{\nu_0}\mu, \Phi_{\nu_0}\nu) \\ &\leq C_{1, T} \mathbb{E}[W_1(\mu_0, \nu_0)] + \gamma_T d_S(\mu, \nu) \end{aligned} \quad (39)$$

In the last inequality we have used (38) and Lemma 19. Inequality (39) leads to

$$d_S(\mu, \nu) \leq \frac{C_{1, T}}{1 - \gamma_T} \mathbb{E}[W_1(\mu_0, \nu_0)]$$

□

Reading the proof of this theorem one may wonder if it is really necessary to add the complication of splitting the time interval in subintervals. Indeed a more simple calculation can lead to a global estimate, although it can only be obtained if the initial conditions belong W_2 , which is a stronger assumption. Nevertheless we will give now the proof in that case so that the reader can compare the two different approaches. Moreover if one is interested in the W_2 norm, one can apply this method to other results within this paper. We are indebted to an anonymous referee for suggesting us this idea.

At the end of this subsection we will stress what is the difficulty encountered using W_1 which prevents us to obtain a straightforward global estimation in time.

Theorem 21. *Under the same assumptions of Theorem 20, suppose that the random measures μ_0, ν_0 take values in $\mathcal{P}_2(\mathbb{R}^d)$, namely they have finite second moments. Then it holds, for all $t \leq T$,*

$$\mathbb{E} [W_2^2(\mu_t, \nu_t)] \leq 4e^{4t(2L_K^2 + C_2 L_\sigma^2)} \mathbb{E} [W_2^2(\mu_0, \nu_0)]$$

where L_K and L_σ are the Lipschitz constants of the coefficients of the system and C_2 is the constant appearing in Burkholder-Davis-Gundy inequality with exponent 2.

Proof. Proceeding as in the proof of Theorem 20, we can find a random measure $m \in \Gamma_0(\mu_0, \nu_0)$, such that $W_2^2(\mu_0, \nu_0) = \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - x'|^2 dm(x, x')$. Moreover it holds

$$\mathbb{E} [W_2^2(\mu_t, \nu_t)] \leq \mathbb{E} \left[\int |X^\mu(t, x) - X^\nu(t, x')|^2 dm \right] = \mathbb{E} \left[\int \mathbb{E} [X^\mu(t, x) - X^\nu(t, x')|^2 \middle| \mathcal{F}_0] dm(x, x') \right].$$

Hence we proceed estimating the conditional expectation in the last term using that $X^\mu(t, x)$ and $X^\nu(t, x')$ solve (26) and a parallelogram inequality,

$$\mathbb{E} [|X^\mu(t, x) - X^\nu(t, x')|^2 | \mathcal{F}_0] \leq 2|x - x'|^2 \quad (40)$$

$$+ 2\mathbb{E} \left[\left(\int_0^t |b_{\mu_s}(X^\mu(s, x)) - b_{\nu_s}(X^\nu(s, x'))| ds \right)^2 | \mathcal{F}_0 \right] \quad (41)$$

$$+ 2\mathbb{E} \left[\left(\int_0^t \sum_k |\sigma_k(X^\mu(s, x)) - \sigma_k(X^\nu(s, x'))| dB_s^k \right)^2 | \mathcal{F}_0 \right]. \quad (42)$$

Using a Burkholder-Davis-Gundy inequality and the Lipschitz continuity of σ_k , we can estimate (42) as follows

$$2\mathbb{E} \left[\left(\int_0^t \sum_k |\sigma_k(X^\mu(s, x)) - \sigma_k(X^\nu(s, x'))| dB_s^k \right)^2 | \mathcal{F}_0 \right] \leq 2C_2 L_\sigma^2 \mathbb{E} \left[\int_0^t |X^\mu(t, x) - X^\nu(t, x')|^2 ds | \mathcal{F}_0 \right]. \quad (43)$$

To estimate (41) we first apply Jensen inequality, then we need to split the drift using a triangular inequality and then use the Lipschitz continuity of K ,

$$\begin{aligned} 2\mathbb{E} \left[\left(\int_0^t |b_{\mu_s}(X^\mu(s, x)) - b_{\nu_s}(X^\nu(s, x'))| ds \right)^2 | \mathcal{F}_0 \right] &\leq 2t\mathbb{E} \left[\int_0^t |b_{\mu_s}(X^\mu(s, x)) - b_{\nu_s}(X^\nu(s, x'))|^2 ds | \mathcal{F}_0 \right] \\ &\leq 4t\mathbb{E} \left[\int_0^t ds \int |K(X^\mu(s, x) - y) - K(X^\nu(s, x') - y)|^2 d\mu_s(y) \right. \\ &\quad \left. + \left| \int (K(X^\nu(s, x') - y) - K(X^\nu(s, x') - y')) d(\mu_s(y) - \nu_s(y')) \right|^2 | \mathcal{F}_0 \right] \\ &\leq 4tL_k^2 \int_0^t \mathbb{E} [|X^\mu(s, x) - X^\nu(s, x')|^2 | \mathcal{F}_0] ds \quad (44) \\ &\quad + 4tL_k^2 \int_0^t \mathbb{E} [W_2^2(\mu_s, \nu_s) | \mathcal{F}_0] ds. \quad (45) \end{aligned}$$

We used here a property of the Wassertein metric which we already used and proved in the proof of Lemma 18 (see (29)) for W_1 , but which can be straightforwardly readapted to W_2 .

We now put together (40), (44), (45) and (43) to obtain

$$\begin{aligned} \mathbb{E} [W_2^2(\mu_t, \nu_t)] &\leq \mathbb{E} \left[\int |X^\mu(t, x) - X^\nu(t, x')|^2 dm(x, x') \right] \leq 2\mathbb{E} [W_2^2(\mu_0, \nu_0)] \\ &\quad + 4tL_k^2 \int_0^t \mathbb{E} \left[W_2^2(\mu_s, \nu_s) + \int |X^\mu(s, x) - X^\nu(s, x')|^2 dm(x, x') \right] ds \\ &\quad + 2C_2 L_\sigma^2 \int_0^t \mathbb{E} \left[\int |X^\mu(s, x) - X^\nu(s, x')|^2 dm(x, x') \right] ds. \end{aligned}$$

Adding at the end the positive term $2C_2 L_\sigma^2 \int_0^t \mathbb{E} [W_2^2(\mu_s, \nu_s)] ds$, we can apply Gronwall inequality and obtain

$$\mathbb{E} \left[W_2^2(\mu_t, \nu_t) + \int |X^\mu(t, x) - X^\nu(t, x')|^2 dm(x, x') \right] \leq 4e^{4t(2tL_k^2 + C_2 L_\sigma^2)} \mathbb{E} [W_2^2(\mu_0, \nu_0)].$$

□

Remark 22. Reading the proof of the previous Theorem one can be led to think that it is possible to do the same calculations using the norm W_1 , which is true up to some point. In particular, following the idea of the

proof of Theorem 21 one can reach the inequality

$$\begin{aligned} \mathbb{E}[W_1(\mu_t, \nu_t)] &\leq \mathbb{E}\left[\int |X_t^\mu - X_t^\nu| dm\right] \leq \mathbb{E}[W_1(\mu_0, \nu_0)] + L_k \int_0^t \mathbb{E}\left[W_1(\mu_s, \nu_s) + \int |X_s^\mu - X_s^\nu| dm\right] ds \\ &\quad + C_1 L_\sigma \mathbb{E}\left[\int \left(\int_0^t |X_s^\mu - X_s^\nu|^2 ds\right)^{\frac{1}{2}} dm\right]. \end{aligned}$$

The difficult term is the last one, indeed we do not see a way to get rid of the powers or to switch them with the integrals. What we indeed do in most of the proofs in this paper is to take the supremum in time inside the integrals to obtain

$$\mathbb{E}\left[\int \left(\int_0^t |X_s^\mu - X_s^\nu|^2 ds\right)^{\frac{1}{2}} dm\right] \leq t C_1 L_\sigma \mathbb{E}\left[\int \sup_{s \in [0, t]} |X_s^\mu - X_s^\nu| dm\right].$$

At this point it is no longer possible to apply Gronwall Lemma, but this last term can be subtracted in both sides of the estimations to get something of the form $(1 - t C_1 L_\sigma) \mathbb{E}\left[\int \sup_{s \in [0, t]} |X_s^\mu - X_s^\nu| dm\right] \leq \dots$, from which the need to do the estimations in small intervals first.

4.1 Propagation of chaos

Let $(\Omega, \mathcal{F}, \mathcal{F}_t, \mathbb{P})$ be a filtered probability space, and $(X_0^i)_{i \in \mathbb{N}}$ be a sequence of symmetric \mathbb{R}^d -valued random variable on this space that are measurable with respect to \mathcal{F}_0 . We consider a collection B_t^k , $k \geq 1$, of independent Brownian motions on this space, independent from the X_0^i , and we call $(\mathcal{F}_t^B)_{t \geq 0}$ the filtration generated by $(B_t^k)_{k \geq 1}$. For every $N \in \mathbb{N}$, $X^N = (X_t^{1,N}, \dots, X_t^{N,N})_{t \geq 0}$ is the solution of equation (1) with initial condition (X_0^1, \dots, X_0^N) . We will further suppose that the empirical measure $S_0^N := \frac{1}{N} \sum_{i=0}^N \delta_{X_0^i}$ converges to a random probability measure μ_0 , in the metric $\mathbb{E}[W_1(\cdot, \cdot)]$. Under this settings we will now prove Theorem 24 (which is slightly more general then Theorem 2) and 3, but first we need the following lemma.

Lemma 23. *Let $\sigma : \{1, \dots, N\} \rightarrow \{1, \dots, N\}$ be a permutation. Then,*

$$\mathbb{E}\left[f(X_t^{1,N}, \dots, X_t^{N,N}) | \mathcal{F}_t^B\right] = \mathbb{E}\left[f(X_t^{\sigma(1),N}, \dots, X_t^{\sigma(N),N}) | \mathcal{F}_t^B\right], \quad (46)$$

for every $f \in C_b((\mathbb{R}^d)^N)$.

Proof. Let $X^{\sigma,N} := (X_t^{\sigma(1),N}, \dots, X_t^{\sigma(N),N})_{t \geq 0}$. Since X^N is a strong solution of equation (1) with initial condition (X_1, \dots, X_N) it is easy to see that $X^{\sigma,N}$ is a strong solution of equation (1) with initial condition $(X_{\sigma(1)}, \dots, X_{\sigma(N)})$. Since the coefficients b and σ_k have the necessary Lipschitz properties (see [12]), we have strong uniqueness at fixed initial data $x \in \mathbb{R}^d$. Thus, we can apply Proposition 1.4 of [16] (notice that X^N and $X^{\sigma,N}$ have the same initial law) and we obtain uniqueness in law. More precisely we have,

$$(X_t^N, (B_t^k)_{k \in \mathbb{N}})_{\#} \mathbb{P} = (X_t^{\sigma,N}, (B_t^k)_{k \in \mathbb{N}})_{\#} \mathbb{P} \quad \forall t \geq 0.$$

This implies, for every $A \in \mathcal{F}_t^B$ such that $A = \{(B_t^k)_{k \geq 1} \in \tilde{A}\}$ with $\tilde{A} \in \mathcal{B}((\mathbb{R}^d)^\infty)$ and for every $\phi \in C_b((\mathbb{R}^d)^N)$,

$$\mathbb{E}\left[\mathbb{1}_A f(X_t^N)\right] = \mathbb{E}\left[\mathbb{1}_{\{(B_t^k)_{k \geq 1} \in \tilde{A}\}} f(X_t^N)\right] = \mathbb{E}\left[\mathbb{1}_{\{(B_t^k)_{k \geq 1} \in \tilde{A}\}} f(X_t^{N,\sigma})\right] = \mathbb{E}\left[\mathbb{1}_A f(X_t^{N,\sigma})\right].$$

Since the integrals of $f(X_t^N)$ and $f(X_t^{N,\sigma})$ coincide on every element of a basis of \mathcal{F}_t^B their conditional expectation coincide too, hence (46) follows. \square

Using the previous result we can now prove Theorem 2 which we restate here for simplicity,

Theorem 24. *There exists a random measure-valued solution μ_t of equation (8) such that*

$$\lim_{N \rightarrow \infty} E [|\langle S_t^N, \phi \rangle - \langle \mu_t, \phi \rangle|] = 0$$

for all $\phi \in C_b(\mathbb{R}^d)$.

Moreover, given $r \in \mathbb{N}$ and $\phi_1, \dots, \phi_r \in C_b(\mathbb{R}^d)$, we have

$$\lim_{N \rightarrow \infty} E \left[\phi_1(X_t^{1,N}) \dots \phi_r(X_t^{r,N}) \middle| \mathcal{F}_t^B \right] = E \left[\prod_{i=1}^r \langle \mu_t, \phi_i \rangle \middle| \mathcal{F}_t^B \right]$$

in $L^1(\Omega)$.

Proof. Since the convergence in the Wasserstein metric W_1 implies the weak convergence, the first statement follows from Theorem 20.

Without loss of generality, we proof the second statement in the case $r = 2$. Let $\phi_1, \phi_2 \leq M$. By a triangular inequality we obtain

$$\begin{aligned} & \left| E \left[\phi_1(X_t^{1,N}) \phi_2(X_t^{2,N}) \middle| \mathcal{F}_t^B \right] - E \left[\langle \mu_t, \phi_1 \rangle \langle \mu_t, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] \right| \\ & \leq \left| E \left[\phi_1(X_t^{1,N}) \phi_2(X_t^{2,N}) \middle| \mathcal{F}_t^B \right] - E \left[\langle S_t^N, \phi_1 \rangle \langle S_t^N, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] \right| \end{aligned} \quad (47)$$

$$+ \left| E \left[\langle S_t^N, \phi_1 \rangle \langle S_t^N, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] - E \left[\langle \mu_t, \phi_1 \rangle \langle \mu_t, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] \right|. \quad (48)$$

Using Lemma 23 we can estimate (47) as follows

$$\begin{aligned} & \left| E \left[\phi_1(X_t^{1,N}) \phi_2(X_t^{2,N}) \middle| \mathcal{F}_t^B \right] - E \left[\langle S_t^N, \phi_1 \rangle \langle S_t^N, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] \right| \\ & = \left| \frac{1}{N^2 - N} \sum_{i,j=1, i \neq j}^N E \left[\phi_1(X_t^{i,N}) \phi_2(X_t^{j,N}) \middle| \mathcal{F}_t^B \right] - \frac{1}{N^2} \sum_{i,j=1}^N E \left[\phi_1(X_t^{i,N}) \phi_2(X_t^{j,N}) \middle| \mathcal{F}_t^B \right] \right| \\ & \leq \left| \left(\frac{1}{N^2 - N} - \frac{1}{N^2} \right) (N^2 - N) M^2 \right| + \left| \frac{1}{N} M^2 \right| = 2 \frac{M^2}{N} \rightarrow 0, \quad \text{as } N \rightarrow \infty. \end{aligned}$$

The convergence to zero of (48) follows from the first statement of this theorem, indeed,

$$\begin{aligned} & E \left[\left| E \left[\langle S_t^N, \phi_1 \rangle \langle S_t^N, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] - E \left[\langle \mu_t, \phi_1 \rangle \langle \mu_t, \phi_2 \rangle \middle| \mathcal{F}_t^B \right] \right| \right] \\ & \leq E \left[\left| \langle S_t^N, \phi_1 \rangle - \langle \mu_t, \phi_1 \rangle \right| \left| \langle S_t^N, \phi_2 \rangle \right| \right] + E \left[\left| \langle S_t^N, \phi_2 \rangle - \langle \mu_t, \phi_2 \rangle \right| \left| \langle \mu_t, \phi_1 \rangle \right| \right] \\ & \leq M E \left[\left| \langle S_t^N, \phi_1 \rangle - \langle \mu_t, \phi_1 \rangle \right| \right] + M E \left[\left| \langle S_t^N, \phi_2 \rangle - \langle \mu_t, \phi_2 \rangle \right| \right] \\ & = 2 M E \left[\left| \langle S_t^N, \phi_1 \rangle - \langle \mu_t, \phi_1 \rangle \right| \right] \rightarrow 0 \quad \text{as } N \rightarrow \infty. \end{aligned}$$

□

Proof of Theorem 3. First notice that $X^{r,N}$ is the strong solution of equation (26) with drift coefficient b_ν , where $\nu = S^N = \{S_t^N\}_{t \in [0,T]}$, and initial condition X_0^r . We can thus write $X^{r,N} = X^\nu(t, X_0^r(\omega), \omega)$.

If we apply Lemma 18, we obtain,

$$E \left[\left| X_t^{r,N} - X_t \right| \right] \leq \gamma_T d_S(\mu, S^N)$$

This last quantity goes to 0 as $N \rightarrow \infty$ thanks to Theorem 20.

□

4.2 Quantitative estimates

As already mentioned there are several recent result in literature that deal with the rate of convergence of an empirical measure, in this Section we want to give some examples of how this results can be applied in our model using Theorem 20. Under the assumption on the beginning of the Section, we further define G_0^N

the law of the initial condition (X_0^1, \dots, X_0^N) and we denote by $G_{0,2}^N$ its first two marginals. Given a $p > 0$, we suppose that G_0^N and μ_0 have finite first p moments $M_p(G_0^N)$ and $M_p(\mu_0)$.

Using Theorem 2.4 of [11] on the initial conditions and our estimates of Theorem 20 we can compare the rate of convergence of the empirical measure of the solution to the rate of convergence of just two initial particles.

Corollary 25. *For every exponent $\gamma < (d+1 + \frac{d}{p})^{-1}$ there exists a finite positive constant Γ depending only on p and d such that, for every $N \geq 1$,*

$$\mathbb{E}[W_1(S_t^N, \mu)] \leq \tilde{C}\Gamma (M_p(G_0^N) + M_p(\mu_0))^{\frac{1}{p}} \left(W_1(G_{0,2}^N, \mu_0) + \frac{1}{N} \right)^\gamma$$

When the initial condition consists of a sequence of i.i.d. μ_0 -distributed random variables $(X_0^i)_{i \in \mathbb{N}}$, a quantitative estimate can be derived from [9]. Under this stronger assumptions one can obtain a slightly stronger result, however in this case we must suppose that the measures which we are working on have finite p moments with p strictly greater than one.

Corollary 26. *Let $p > 1$. There exists a constant Γ depending on p and d such that, for all $N \geq 1$,*

$$\mathbb{E}[W_1(S_t^N, \mu_t)] \leq \tilde{C}\Gamma M_p(\mu_0)^{\frac{1}{p}} \begin{cases} N^{-\frac{1}{2}} \log(1+N) + N^{-\frac{(p-1)}{p}} & \text{if } d = 2 \text{ and } p \neq 2 \\ N^{-\frac{1}{d}} + N^{-\frac{(p-1)}{p}} & \text{if } d > 2 \text{ and } p \neq \frac{d}{d-1} \end{cases}$$

A Appendix

Proposition 27. *Given $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \in [0, T]}, \mathbb{P})$, let M_t be a continuous martingale with respect to \mathcal{F}_t . If we define $M_t^* = \sup_{0 \leq s \leq t} |M_s|$, it holds*

$$\mathbb{E}[|M_t^*|^p | \mathcal{F}_0] \leq C_p \mathbb{E}\left[|M_t|^{\frac{p}{2}} | \mathcal{F}_0\right],$$

for some constant $C_p > 0$.

Proof. We fix an $A \in \mathcal{F}_0$ and we prove the following

$$\mathbb{E}[\mathbf{1}_A |M_t^*|^p] \leq C_p \mathbb{E}[\mathbf{1}_A |M_t|^{\frac{p}{2}}]$$

First we note that $N_t := M_t \mathbf{1}_A$ is a continuous \mathcal{F}_t -martingale, indeed $A \in \mathcal{F}_0 \subset \mathcal{F}_s$ implies

$$\mathbb{E}[\mathbf{1}_A M_t | \mathcal{F}_s] = \mathbf{1}_A \mathbb{E}[M_t | \mathcal{F}_s] = \mathbf{1}_A M_s$$

We can thus apply the Burkholder-Davis-Gundy inequality to N_t and we obtain

$$\mathbb{E}[|N_t^*|^p] \leq C_p \mathbb{E}\left[|N_t|^{\frac{p}{2}}\right]$$

Notice that $\mathbf{1}_A$ commute with $\sup_{t \in [0, T]}$. The thesis follows from the equality

$$[\mathbf{1}_A M]_t = \mathbf{1}_A [M]_t. \tag{49}$$

□

Throughout the paper we repeatedly used an identity of the form

$$E\left[\int_{\mathbb{R}^d} f(x) d\mu_0(x) | \mathcal{F}_0\right] = \int_{\mathbb{R}^d} E[f(x) | \mathcal{F}_0] d\mu_0(x). \tag{50}$$

This identity may look at first sight completely general but it requires appropriate assumptions of continuity in x and integrability. Just in order that all objects are well defined, we need:

- i) $f : \Omega \rightarrow C(\mathbb{R}^d)$ measurable
- ii) $E \left[\int_{\mathbb{R}^d} |f(x)| d\mu_0(x) \right] < \infty$
- iii) $E \left[\sup_{x \in K} |f(x)| \right] < \infty$ for every compact set $K \subset \mathbb{R}^d$.

Indeed, under (i)-(ii), the integral $\int_{\mathbb{R}^d} f(x) d\mu_0(x)$ is first well defined and finite a.s. (f has to be continuous in x since μ_0 is a general probability measure), and also $L^1(\Omega)$, so the conditional expectation $E \left[\int_{\mathbb{R}^d} f(x) d\mu_0(x) | \mathcal{F}_0 \right]$ is well defined. As to the right-hand-side of (50), on any compact set $K \subset \mathbb{R}^d$, from (i) and (iii) we have $\omega \mapsto f(\omega, \cdot)$ of class $L^1(\Omega; C(K))$ (the space $C(K)$ of continuous functions on K endowed with the uniform topology), hence by the definition of conditional expectation of random variables with values in Banach spaces, $E[f|_K | \mathcal{F}_0]$ is again a well defined element of $L^1(\Omega; C(K))$; and, as shown below in the proof of next proposition, taking as compact sets the sequence of closed balls $B(0, n)$ one gets a definition of $E[f(x) | \mathcal{F}_0]$ as a measurable function from Ω to $C(\mathbb{R}^d)$; notice in particular that continuity in x of $E[f(x) | \mathcal{F}_0]$ is essential to define $\int_{\mathbb{R}^d} E[f(x) | \mathcal{F}_0] d\mu_0(x)$ because μ_0 is a general probability measure. Finally, the finiteness of $\int_{\mathbb{R}^d} E[f(x) | \mathcal{F}_0] d\mu_0(x)$ is ultimately a consequence of (ii) again, as proved in the next proposition.

Proposition 28. *Under assumptions (i)-(ii)-(iii), identity (50) holds true almost surely.*

Proof. As already noticed, given $n \in \mathbb{N}$, $E[f|_{B(0,n)} | \mathcal{F}_0]$ is a well defined element of $L^1(\Omega; C(B(0, n)))$. Moreover, if g is in the equivalence class of $E[f|_{B(0,n)} | \mathcal{F}_0]$ then at any $x \in B(0, n)$ we have that $g(x)$ is in the equivalence class of $E[f(x) | \mathcal{F}_0]$ (understood as the conditional expectation of the r.v. $\omega \mapsto f(\omega, x)$, x given). Indeed, for every $A \in \mathcal{F}_0$,

$$\mathbb{E}[g(x)\mathbb{1}_A] = \mathbb{E}[g\mathbb{1}_A](x) = \mathbb{E}[f\mathbb{1}_A](x) = \mathbb{E}[f(x)\mathbb{1}_A]$$

We can choose a sequence $f^{(m)} = \sum_{i=1}^m f_i \mathbb{1}_{A_i}$ such that $f_i \in C(B(0, n))$, $A_i \in \mathcal{F}$ and $f^{(m)} \rightarrow f$ in $L^1(\Omega, C(B(0, n)))$, as $m \rightarrow \infty$. Moreover one can choose, up to subsequences, $f^{(m)}$ such that the convergence is almost sure and $\|f^{(m)}\|_\infty \leq \|f|_{B(0,n)}\|_\infty$, a.s.. It is easy to see that $\mathbb{E}[f^{(m)} | \mathcal{F}_0] = \sum_i \mathbb{E}[f_i | \mathcal{F}_0] \mathbb{1}_{A_i}$. From this it follows that,

$$\mathbb{E} \left[\int_{B(0,n)} f^{(m)} d\mu_0 \middle| \mathcal{F}_0 \right] = \int_{B(0,n)} \mathbb{E} [f^{(m)} | \mathcal{F}_0] d\mu_0, \quad \mathbb{P} - \text{a.s.}$$

Notice that, for every fixed ω , it holds $f^{(m)}(\omega) \rightarrow f(\omega)$ uniformly in x on the compact $B(0, n)$, and hence, by the dominated convergence theorem $\int_{B(0,n)} f^{(m)}(\omega)(x) \mu_0(\omega, dx) \rightarrow \int_{B(0,n)} f(\omega)(x) \mu_0(\omega, dx)$. Thus $\int_{B(0,n)} f^{(n)} d\mu_0 \rightarrow \int_{B(0,n)} f d\mu_0$ in L^1 from which follows that, up to a subsequence, $\mathbb{E} \left[\int_K f^{(n)} d\mu_0 \middle| \mathcal{F}_0 \right] \rightarrow \mathbb{E} \left[\int_{B(0,n)} f d\mu_0 \middle| \mathcal{F}_0 \right]$, \mathbb{P} -a.s.. On the other hand, we can first apply conditional dominated convergence and then the traditional version of it to obtain $\int_{B(0,n)} \mathbb{E} [f^{(n)} | \mathcal{F}_0] d\mu_0 \rightarrow \int_{B(0,n)} \mathbb{E} [f | \mathcal{F}_0] d\mu_0$.

We have proven (50) on a closed ball of \mathbb{R}^d , we want to extend it on the whole space. Given $n \in \mathbb{N}$, we call f_n the restriction of f on $B(0, n)$. It holds, as already noted, $f_n \in L^1(\Omega, C(B(0, n)))$ for every $n \in \mathbb{N}$.

We construct now the sequence $\{g_n\}_{n \in \mathbb{N}}$ such that $g_n : \Omega \rightarrow C(B(0, n))$ and

$$\begin{aligned} g_n &\in L^1(\Omega; C(B(0, n))) && \text{for every } n \in \mathbb{N} \\ g_n &\in E[f_n | \mathcal{F}_0] && \text{for every } n \in \mathbb{N}. \end{aligned}$$

We will show that there exists a function $g : \Omega \rightarrow C(\mathbb{R}^d)$, such that for every $x \in \mathbb{R}^d$, $g(x) \in E[f(x) | \mathcal{F}_0]$ and $g|_{\Omega \times B(0,n)} = g_n$. Moreover if $g, g' : \Omega \rightarrow C(\mathbb{R}^d)$ have the same properties, then $g = g'$ a.s.

First, let us prove that $g_{n+1}|_{\Omega \times B(0,n)}$, as a function from Ω to $C(B(0, n))$, is equal to g_n on a set Ω_n of measure one. The function g_{n+1} is characterized by two properties: it is \mathcal{F}_0 -measurable, and $E[g_{n+1} \mathbb{1}_A] = E[f_{n+1} \mathbb{1}_A]$ for every $A \in \mathcal{F}_0$. Here $E[g_{n+1} \mathbb{1}_A]$ and $E[f_{n+1} \mathbb{1}_A]$ are elements of $C(B(0, n+1))$. Similarly, g_n is \mathcal{F}_0 -measurable, and $E[g_n \mathbb{1}_A] = E[f_n \mathbb{1}_A]$ for every $A \in \mathcal{F}_0$. Obviously $g_{n+1}|_{\Omega \times B(0,n)}$ is \mathcal{F}_0 -measurable. Moreover,

$$E[g_{n+1}|_{\Omega \times B(0,n)} \mathbb{1}_A] = E[g_{n+1} \mathbb{1}_A] |_{B(0,n)}$$

To show this, notice that the function

$$G_n(x) := \mathbb{E}[g_{n+1}(x) | \Omega \times B(0, n) \mathbb{1}_A]$$

is well defined by Fubini theorem as a function from $B(0, n)$ to \mathbb{R}^d . In the same way one can define $G(x) := \mathbb{E}[g_{n+1}(x)\mathbb{1}_A]$ as a function on $B(0, n+1)$. Now $G_n(x) = G(x)$ for every $x \in B(0, n)$, hence $G_n = G|_{B(0, n)}$. Now,

$$E[g_{n+1}\mathbb{1}_A]|_{B(0, n)} = E[f_{n+1}\mathbb{1}_A]|_{B(0, n)} = E[f_{n+1}|\Omega \times B(0, n)\mathbb{1}_A] = E[f_n\mathbb{1}_A] = E[g_n\mathbb{1}_A]$$

and thus $g_{n+1}|_{\Omega \times B(0, n)}$ is almost surely equal to g_n .

On the set $\cap_n \Omega_n$, we have $g_m|_{\Omega \times B(0, k)} = g_k$ for every $m \geq k \geq 0$. Let $g : \Omega \times \mathbb{R}^d \rightarrow \mathbb{R}$ be defined on $\cap_n \Omega_n$ as $g(x, \omega) = g_m(x, \omega)$ where m is the smallest integer such that $x \in B(0, m)$ (and arbitrarily on the complementary of $\cap_n \Omega_n$). For every $\omega \in \cap_n \Omega_n$ the function $x \mapsto g(x, \omega)$ is continuous on each $B(0, m)$ (easy to check by the previous properties). Hence $g : \Omega \rightarrow C(\mathbb{R}^d)$.

Now, if $g' : \Omega \rightarrow C(\mathbb{R}^d)$ is such that, for every $n \in \mathbb{N}$, it holds $g'|_{\Omega \times B(0, n)} \in \mathbb{E}[f_n|\mathcal{F}_0]$, then there exists a set $\Omega_n \subset \Omega$, such that $\mathbb{P}(\Omega_n) = 1$ and $g_n = g'_n$ on Ω_n . Then for every $\omega \in \cap_n \Omega_n$, and for every $x \in B(0, n)$, $g(\omega, x) = g_n(\omega, x) = g'_n(\omega, x) = g'(\omega, x)$, hence $g = g'$ a.e. Finally, if $x \in B(0, n)$, and $A \in \mathcal{F}_0$,

$$\mathbb{E}[g(x)\mathbb{1}_A] = \mathbb{E}[g_n(x)\mathbb{1}_A] = \mathbb{E}[g_n\mathbb{1}_A](x) = \mathbb{E}[f_n\mathbb{1}_A](x) = \mathbb{E}[f_n(x)\mathbb{1}_A] = \mathbb{E}[f(x)\mathbb{1}_A].$$

Hence $g(x) \in \mathbb{E}[f(x)|\mathcal{F}_0]$. To conclude we notice that, applying Lebesgue dominate convergence theorem to the sequence f_n , the random variables $\int_{B(0, n)} f_n d\mu_0$ converges a.s. to the random variable $\int_{\mathbb{R}^d} f d\mu_0$, as $n \rightarrow \infty$. Thus, by the conditional version of dominated convergence theorem,

$$\mathbb{E}\left[\int_{\mathbb{R}^d} f d\mu_0 \middle| \mathcal{F}_0\right] = \lim_{n \rightarrow \infty} \mathbb{E}\left[\int_{B(0, n)} f_n d\mu_0 \middle| \mathcal{F}_0\right] \quad (51)$$

By the definition of g , we have that, as $n \rightarrow \infty$, the positive part g_n^+ increases to g^+ a.s., and the negative g_n^- increases to g^- . Thus by monotone convergence theorem, it holds a.s.,

$$\int_{\mathbb{R}^d} g d\mu_0 = \int_{\mathbb{R}^d} g^+ d\mu_0 - \int_{\mathbb{R}^d} g^- d\mu_0 = \lim_{n \rightarrow \infty} \int_{B(0, n)} g_n^+ d\mu_0 - \lim_{n \rightarrow \infty} \int_{B(0, n)} g_n^- d\mu_0, \quad (52)$$

The thesis follows from the equalities (51) and (52). Notice that this also implies that $\int_{\mathbb{R}^d} \mathbb{E}[f(x)|\mathcal{F}_0] d\mu_0(x)$ is finite, because it is equal to a finite quantity. \square

Proposition 29. Let $(\mu, \nu) \in \mathcal{P}_1(\mathbb{R}^d)$. If we define the set

$$\Gamma_0(\mu, \nu) := \left\{ \bar{m} \in \Gamma(\mu, \nu) \middle| \int_{\mathbb{R}^{2d}} |x - y| d\bar{m}(x, y) = \inf_{m \in \Gamma(\mu, \nu)} \int_{\mathbb{R}^{2d}} |x - y| dm(x, y) \right\}$$

then there exists a measurable function $f : \mathcal{P}_1(\mathbb{R}^d) \times \mathcal{P}_1(\mathbb{R}^d) \rightarrow \mathcal{P}_1(\mathbb{R}^{2d})$ such that $f(\mu, \nu) \in \Gamma_0(\mu, \nu)$.

Proof. The set $\{(\mu, \nu, m) | m \in \Gamma_0(\mu, \nu)\}$ is closed in $\mathcal{P}_1(\mathbb{R}^d) \times \mathcal{P}_1(\mathbb{R}^d) \times \mathcal{P}_1(\mathbb{R}^{2d})$ endowed with the weak topology (see e.g. [1], Proposition 7.1.3), thus the Proposition follows from Von Neumann Theorem on measurable selections. \square

Acknowledgments. The authors wish to thank the anonymous referees for the careful revision which helped to clarify and improve considerably the initial version of this paper.
